THE law which at present governs the practice of medicine in France forbids the simultaneous practice of medicine and pharmacy even by a person who may be in possession of diplomas in both subjects. As this law expressly prohibits any mutual arrangement between a medical man and a pharmaceutical chemist, as well as any partnership between them for the carrying on of a dispensary or the sale of medicine, it is evident that this prohibition is applicable most of all to the case where the mutual understanding is inevitable—that is, to the case where the medical man and the druggist are one and the same person. Unfortunately the statute does not specify any penalty for infringement, but merely declares that arrangements of the kind already described are of no effect in a legal sense. The consequence is that the criminal courts cannot pass sentence on persons brought before them for practising both medicine and pharmacy, and the culprits have to be discharged although their guilt is manifest, so that the practice in question is to all intents and purposes authorised. This state of things might answer in places where there is no pharmaceutical chemist but would be unsatisfactory in towns, for the medical man is reduced to the position of a dealer in drugs and there is no proper supervision over the dispensing of prescriptions, as the responsible head of the establishment would not be in attendance; moreover, the prescriptions are no longer checked by a druggist who is able in the interests of the patients to correct any error which may have been accidentally made. The medical syndicate of Roubaix has accordingly just presented a petition to the Senate and the Chamber of Deputies praying for an amendment of the law passed three years ago to regulate the practice of medicine and pharmacy in France. This petition sets forth the arguments which I have just been enumerated, and mentions that the courts were formerly able to enforce the law by passing sentences of six months' imprisonment in such cases.

The Trial of a Medical Man.

The sentence upon Dr. Laporte has just been pronounced. Your readers will doubtless remember the course of events which led up to the trial, but to give a short *résumé* they were as follows. Dr. Laporte was called in the middle of

Digitized by Google

the night to a woman in labour. He had to perform craniotomy, and not possessing the proper instruments had to make shift with those at hand, among which was a long needle of the kind used by mattress-makers. The woman died two days later, and the experts who made the post-mortem examination gave evidence that they found two perforations in the bladder caused by the needle. The immediate arrest of Dr. Laporte, his imprisonment for three weeks despite all the protests which the medical men of Paris made to the judge, brought about a strong feeling of resentment at the action of the authorities, not only among the medical men of Paris, but also among the general public. The evidence given at the trial was of the most sensational character. That for the prosecution was given by the husband of the victim and two neighbours who were in the room, but whom Dr. Laporte asked to retire at the time of his performing the operation. These, however, said that they left the door ajar, and so could see everything that went on; they testified that Dr. Laporte used the forceps in an altogether wrong manner, and that, in addition, his instruments were defective! It was shown that the husband had left his wife in labour all day long, that all her previous confinements had been difficult and had necessitated the use of instruments, and that he had only waited until night fell so as to be able to send for a medical man belonging to the *service de nuit* because he could get him for nothing. For the defence sundry expert witnesses said that Dr. Laporte was perfectly justified in performing craniotomy and in using such instruments as were at hand. All the trial turned upon the question whether Dr. Laporte in introducing the needle into the vagina had guided it with his finger so as to avoid wounding the neighbouring organs, or whether he had pushed it in haphazard, as the two gossips who were outside the door said he did. In vain did Professor Pinard, the head accoucheur at the Maternity Hospital, give it as his opinion that Dr. Laporte must have guided the needle otherwise he would have perforated the rectum; in vain did he say that the perforations found in the bladder were probably not produced by the needle, but were spontaneous, finally declaring on oath that Dr. Laporte had acted in every way as a thoroughly expert accoucheur, for after having applied the forceps four times the vagina and neighbouring organs exhibited no trace of injury. Despite this important declaration, and despite the affirmation of Dr. Laporte that he had guided the needle with his finger, the court adopted exclusively the view of the two witnesses outside the door and sentenced Dr. Laporte to three months' imprisonment. It took into consideration, however, his former blameless conduct and the humanity he had shown in doing his utmost to save the woman without hesitating on account of the risks he knew he must have been running. The judge gave the accused the benefit of the law of *sursis*, which in France allows sentence to be deferred in the case of a first offender of good antecedents for the space of five years, and at the end of that time the remission of the penalty completely if no new crime has been alleged against the accused during that time. Dr. Laporte has appealed against this judgment, which has aroused a great deal of public feeling. Every medical society of Paris has issued a strongly worded protest, and a subscription has been got up amongst medical men for the purpose of offering Dr. Laporte such a sum as will enable him to buy any instrument he may lack and to better his circumstances all round. Dr. Laporte, however, has obsolutely refused to receive any such thing.

A Modern Werewolf.

The authorities have recently arrested in the provinces a man named Vacher, for whom they had been looking for some time, and who has made a sinister reputation for himself under the name of the "shepherd slaughterer." He is acknowledged to be the author of nineteen murders, accompanied for the most part by violation, and every day new crimes, of which the authors have up to now been unknown, are attributed to him, all of which he acknowledges with a kind of pride, saying that he did them under the impulse of a command from Heaven and while he was in a kind of trance. All his victims were lonely wayfarers, young men, young girls, children, and old women. He often used to open the bellies of his victims in order to glut his lust for blood among the abdominal viscera. Vacher had formerly injured his head in various ways, one of the injuries received being from two revolver bullets, one of which has not yet been extracted. He was for two years in an asylum, but was discharged by the medical superintendent as cured. He was also for some time under vows in a religious house. At the present moment the question of his responsibility is being hotly debated by lawyers and authorities on forensic medicine. It is, however, obvious that Vacher himself supplies the proofs, for the very exaggeration of his monstrous actions would lead one to suppose that he was of unsound mind, and it may well be asked whether the very complacency with which he takes upon himself every unpunished crime is not simply due to braggadocio and a desire to pose as something more than an ordinary murderer.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The International Conference on Leprosy.[1]

THE next subject of discussion was the Etiology of Leprosy. Professor Neisser, of Breslau, stated that the bacillus found in leprosy was regarded by the majority of medical men as the cause of the disease, but the attempts that have been made to obtain cultures of the bacilli and to communicate leprosy to animals by inoculation have failed. The bacilli are present in every case of leprosy; in two cases observed by Professor Kaposi they could not be discovered at first, but they appeared before the patient's death. Climate, personal or national habits, food, &c., were only of secondary importance in the production of the disease. The tubercular and anæsthetic forms of leprosy were caused by bacilli of varying degrees of virulence.—Dr. Sticker was of opinion that the primary affection in leprosy consisted in a specific ulceration of the mucous membrane of the nose. This ulceration may be present several years before the first tumours appear. He has discovered the bacilli of leprosy in the secretion of the nose in 128 out of 153 cases. From the primary ulceration in the nose the bacilli make their way by means of the lymphatic vessels into other parts of the body. Infection was due, as a rule, to a direct transference of bacilli from the noses of lepers into those of healthy persons; indirect infection by handkerchiefs, &c., was exceptional.—Dr. Arning, of Hamburg, stated that he had seen primary affections in other parts of the body, as, for instance, on the arm.—Dr. Schaeffer, of Breslau, expressed the opinion that the bacilli were disseminated by patients in the acts of respiration, expectoration, and sneezing, and that disinfection of the mucous membrane of the nose, the pharynx, and the respiratory organs would have the effect of diminishing the number of bacilli spread abroad in this way. These considerations seemed to be of some importance with reference to prophylactic measures.—Dr. Geill, of the Dutch Indies, stated that in 50 per cent. of his cases the first symptom appeared on the feet; he mentioned that the natives who came under his observation were in the habit of walking barefoot, and he also said that in several cases the primary symptom took the form of a pemphigus blister. In almost every case a lesion of the skin of the sole of the foot was found. The virus of leprosy, therefore, seemed to be present on the soil and to enter the organism through these lesions of the foot.—Dr. Peterson gave some statistical details, in the course of which he mentioned that of 1200 cases 783 assumed the tubercular and 315 the macular form of leprosy, whilst 94 were of a mixed character. Men seemed to contract the disease more easily than women. The majority of patients were between twenty and forty years of age, but some were attacked at the ages of sixty and seventy years; there were only thirteen patients aged from two to five years.—At the next meeting Heredity in Relation to Leprosy was discussed; it was obvious that this hypothesis was now abandoned by almost all competent authorities.—On the subject of Treatment Dr. Carrasquilla and Dr. Olaja Lawerda, who had come from South America, explained the results obtained by injections of horse serum. It was generally agreed that amelioration of the symptoms had followed the application of this method, but that an actual cure had not yet been obtained.—The discussion of the necessity of isolation has already been reported in my last letter.—At the final meeting the results arrived at by the

[1] Continued from p. 1084.

Digitized by Google

conference were read by the secretaries in German, French, and English. These conclusions were as follows: (1) the bacillus lepræ is the cause of the disease; (2) its life-history and the mode by which it obtains entrance into the body are not yet fully known, but it is very probable that it makes its way through the mucous membrane of the mouth and nose; (3) leprosy is an infectious disease, but not an hereditary one, and there is an increased risk of infection among populations living under unfavourable conditions; and (4) attempts to cure leprosy have not been successful, and the isolation of lepers is necessary, especially when the disease has become prevalent.—Dr. Hansen finally moved the following resolutions, which were unanimously agreed to: (1) in every country where the disease appears to have spread over a considerable area isolation is the best way of preventing an epidemic; (2) a system of compulsory notification and control over isolation as practised in Norway is recommended for adoption by all nations in which there is a sufficient number of medical men; and (3) the authorities of the respective countries in framing regulations with respect to isolation should be guided by the social conditions of each country.

The members of the conference were received on Oct. 14th by the Emperor at the Neue Palais in Potsdam, the journey being made in special trains. A reception was also given by the Chancellor, Prince Hohenlohe, who was present at one of the meetings of the conference.

The late Professor Heidenhain.

Dr. Rudolf Heidenhain, Professor of Physiology in Breslau, who died in that city on Oct. 13th, was one of the most eminent physiologists of Germany. He was born in 1834 and after having completed his curriculum he devoted himself very early to physiological study. His first investigations on the physiology of muscles and nerves brought him so much reputation that he became ordinary professor in Breslau as early as 1858, being then only twenty-four years of age, a fact unprecedented in the annals of German universities. During his long occupation of the chair of physiology in Breslau he greatly improved both the study and the teaching of physiology there, and in conjunction with his pupils published a large number of very important memoirs. His principal works related to the secretion of the glands, pancreas, lacrymal glands, gastric and intestinal glands, the secretion of the kidney, the formation of lymph, the mode of intestinal absorption, and many other questions which would take too long to enumerate. Professor Heidenhain was a fervent advocate of vivisection and one of its most energetic defenders. In his pamphlet "Die Vivisection im Dienste der Heilkunde" he demonstrated the necessity of vivisection as a method of scientific research from which practical medicine has derived enormous benefits. This essay undoubtedly had a large share in maintaining the freedom of scientific research in Germany.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Suspected Poisoning of Three Hundred and Fifty Emigrants.

ON the 18th inst. Genoa was witness of a sad spectacle, fortunately culminating in no such tragic result as at one time seemed imminent. The *Agordat*, an emigrant ship of the "Navigazione Generale Italo-Brasiliana," was to have weighed anchor that afternoon for Rio de Janeiro and Santos, having on board 1400 men, women, and children, mostly of the very poor, in quest of the livelihood vainly sought in the Old World and fondly anticipated in the New. About 600 of the expected number, Southern Italians mainly, had been embarked since the night before, and at 11.30 A.M. of the 18th were served with their forenoon rations, consisting of "pasta al brodo" (a thin consommé with little segments of macaroni floating in it), a few drachms of "carne" (meat), a piece of bread, and a little wine. The scanty meal over, the majority of those who had partaken of it began to feel ill. Presently the symptoms assumed the well-known character of irritant poisoning—tenesmus, with severe pains and vomiting. The chief sufferers were the women and children, whose contortions and cries produced a panic, which soon included the men, themselves, too, labouring under the same symptoms. The scene was a harrowing one and speedily drew on board the harbour authorities with all the medical men within immediate hail. Alimentary poisoning on an extensive scale was at once suspected, and with the least possible delay every cab, tram-car, and vehicle available was utilised for the transport of the sufferers to the Spedale di Pammatone. An interminable file of conveyances, each accommodating a group of pale, panic-stricken, agonised "avvelenati" (poisoned subjects), passed through the main arteries of the city, filling the rapidly increasing crowd of bystanders with compassion and dismay till the hospital was reached. By this time the whole clinical staff of the Pammatone, reinforced by practitioners from every quarter, by all the medical students of the Genoa school, and the collective nursing and transport service attached to the hospital, was in attendance, and not a moment was lost in treating each relay of sufferers case by case as they arrived, the stomach pump, and, failing that, emetics, being steadily put in practice, and all the more aggravated cases (mostly children) provided for in the wards, medical and surgical. Late in the afternoon it was ascertained that no fatality had occurred, and that most of the patients, 350 in all, were doing well. Meanwhile, the Prefect, Signor Garroni, accompanied by the provincial medical referee, Dr. Elia, and other authorities, having seen for themselves the symptoms under which the sufferers were labouring at the Pammatone, proceeded on board the *Agordat* and at once instituted inquiries, from which it was surmised that the poisoning was attributable to the excess of lead used in soldering the metal platters placed before the emigrants. Specimens of these were sent for analytical inspection to the Ufficio d'Igiene; all the utensils on board were impounded and replaced by others, and rigorous disinfection was practised throughout every part of the ship. The ship itself was anchored in mid-harbour and none of the crew or anyone found on board was allowed to leave it till the cause of the "avvelenamento" had been put beyond doubt. That result, however, does not seem to have been attained. Dr. Palladino, Director of the Pharmaceutical Department of the "Spedali Civili," to whom the analyses were entrusted, reports that after every test on his own part and that of his assistants had been applied the hypothesis of metallic poisoning by lead, verdigris, or any such irritant could not be established, nor in the food and drink consumed could any ingredients be detected to explain the violence and widespread incidences of the intestinal symptoms. For the present the "misadventure," distressing and well-nigh tragic in its consequences, remains a mystery, but public indignation is so intense that it is not likely that the last has been heard of it or that fresh investigations will not be started. The whole subject of "emigration," "emigrants," and "emigrant ships" will come before Parliament, and the inevitable committee appointed to report on it will have details to reveal about as harrowing as any brought to light in a kingdom rich in abuses of every kind. It is already known that about 150,000 emigrants leave Italy every year for the Brazils, driven from rural hamlet or manufacturing town by hardness of living, and tempted by the prospect of high wages or speedy profits enabling them to return with capital enough to begin life anew. From 100 to 120 lire (£4 to £4 15*s.*) a head are paid by these poor adventurers as passage-money, and the equivalent they get for it in "maintenance" and "comfort" *en voyage* may be inferred from the fact that after providing for these conditions the emigration companies earn enough to make the traffic an eminently paying one. Such a code of regulations as control British emigration does not exist in Italy—indeed, a North Italian contemporary, commenting on the whole subject, avers that whatever shadow of legislation has been passed in protection of the emigrant is practically a dead letter. How fortunate, adds the writer, that the "misadventure" occurred in the port of Genoa within reach of well-appointed hospitals and not on the high seas. In the latter case we should have had none but "official" accounts of it—the reports of the sufferers (most of them "analfabeti" or unlettered) coming home months after date and mainly by hearsay. Italy annually loses, principally from the Venetian communes and the island of Sardinia, thousands of her most capable peasantry to struggle and sink on South American soil, and little or nothing is done to make home life easier for them or lessen the inducement to encounter such a fate. Surely this is a state of things that legislation should lose not a day in reforming. "The nineteenth century omelette," says an eminent sociologist, "demands a great smashing of eggs." True; but Italy seems to smash far more eggs than her sister Powers—certainly more than her "State omelette" can in any way justify.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Chronic Nephritis.

ACCORDING to Dr. Chvostek chronic arthritis does not depend on the presence of micro-organisms in either the joints or the blood. The finding of bacteria in the joints, either after death or when death is impending, proves nothing, and the hypothesis that a specific micro-organism is the cause of arthritis is untenable. The symptoms of the disease are not constant, the only characteristic feature being a swelling of short duration affecting a joint—a condition which may be induced by toxins altogether apart from living bacteria. On the other hand, Dr. Singer, who has examined the blood, the urine, and the articular exudations in ninety-two cases, states that both staphylococci and streptococci are to be found. In three instances post-mortem examination showed the same bacteria as in the living subject; in one case the synovial membrane contained bacteria, but the exudation was free from them; in a third case there were hæmorrhages with numerous streptococci in the peri-articular tissue. These facts explain why in a great many cases the articular exudations are free from bacteria. The inflammation of the synovial membrane is symptomatic, the infiltrations which contain the bacteria being frequently in the peri-articular tissue. Dr. Singer considers that the erythema multiforme which frequently accompanies arthritis is a typical pyæmic affection of the skin; he is opposed to the view that salicylic preparations have a specific action, and he has seen very favourable results produced by intravenous injections of a mercurial salt.

The Murphy Button.

In an article published in the *Medicinische Wochenschrift* Dr. Marwedel has given an account of the results obtained with the Murphy button in fifty-five operations. In thirty-five cases an anastomosis was made between the stomach and the intestine and in three cases between the gall-bladder and the intestine; in twenty-nine cases there was carcinomatous stenosis. Twenty-three of the thirty-five cases of gastro-enterostomy showed an improvement; two of the cases of cholecystenterostomy showed an improvement, and the remaining one died. The button was usually passed after the lapse of two weeks. According to statistics published by Dr. Brentano cicatricial stenosis resulted in only three among 328 button operations.

Compulsory Insurance and Medical Aid Societies.

At the last meeting of the Medical Chambers Dr. Janovsky, of Prague, called attention to the compulsory insurance of workmen—a subject of which I have already given an account in THE LANCET.[1] On the ground of the disastrous effects which this system of insurance produces on the incomes of medical practitioners Dr. Janovsky proposed a resolution the substance of which was that all the Medical Chambers should be invited to declare that the holding of a permanent appointment in connexion with this work constitutes an ethical misdemeanour, and that such practitioners will consequently be brought before the council of honour. The resolution was unanimously adopted, and the meeting also made arrangements for presenting a petition to Parliament praying for the repeal of the compulsory laws. The following gentlemen were then elected on the committee: Dr. Adler, Dr. Klotzberg, Dr. Kohn, Dr. Lerch, Dr. Mucha, and Dr. Witlacil.

Cyclic Albuminuria.

Dr. Ostwalt has published in the *Klinische Rundschau* a highly interesting paper on the pathology of cyclic albuminuria, a subject our knowledge of which is very imperfect, amounting to little more than the recognition of the fact that the upright position of the body causes albumin to make its appearance in the urine, but that it is absent from the urine at night. In two cases of this condition observed by Dr. Ostwalt the patients suffered from intra-ocular hæmorrhages, sometimes before the appearance of the albumin in the urine and sometimes during the cyclic albuminuria. The urine, which was previously normal, then contained 2·75 grammes of albumin per litre, and there was also oxaluria. Perverted metabolism has the effect of rendering the walls of the vessels unfit for the complete performance of their functions, and albumin consequently makes its way into the urine when the renal vessels are under unfavourable hydrostatic conditions—that is, when the body is in the upright posture.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of the Insane in Russia.

IN the last number of the Russian journal, *Arkhiv Psikhiatrii*, appears an interesting article by Dr. Yakovenko, throwing much light upon the present state of Russian lunatic asylums, and comparing the provision now made by the *zemstvos* for dealing with lunatics with the State of affairs before the days of *zemstvos*. Like so many other modern institutions and methods in Russia the present system dates from that great epoch of reforms which included the emancipation of the serfs in 1861 and the introduction of the system of local self-government by *zemstvos* in 1863. Before that period the care of the insane in Russia was in the hands of a governmental body known as the *Prikaz*, or Ministry of Social Supervision (*Prikaz obshtchestvennago prizriénia*). When the functions of this body passed over to the *zemstvos* there was asylum accommodation in Russia for 1167 patients; now this number has grown to 9050. Formerly the annual sum expended on each patient was 90 roubles (about £9), now it is 215 roubles (over £21). Consequently the total annual cost of the asylum population of Russia is at the present time not far short of 2,000,000 roubles, instead of only a little over 100 000 as formerly. Great improvements have also been introduced in the methods of treating the insane. Forty years ago there was still a tendency to regard lunatics almost in the light of criminals and to treat them as prisoners rather than as the unfortunate victims of disease. All this has now been altered. The chains and ropes, cages and bars, handcuffs and strait-waistcoats which were formerly found in every asylum in constant use are now things of the past and physical restraint is resorted to only in rare cases where it is absolutely necessary. In brief, the treatment of the insane in Russia is now conducted on the same principles of science, common-sense, and humanity as in other countries. But, writes Dr. Yakovenko, there is still a good deal to be done before the asylum accommodation in Russia can be regarded as adequate. He calculates that the number of insane persons in the "governments" under *zemstvo* rule is somewhere between 127,000 and 191,000. Consequently, at the present time only some 7 per cent. of the total number are now treated in asylums. Comparing Russia in this respect with other countries, he finds that in France the proportion of insane under control in asylums to the total number of insane is 40 per cent.; in Switzerland, 58 per cent.; in America, 66 per cent.; and in Scotland it is as high as 83 per cent. The immediate aim of the *zemstvos*, the article concludes, should be at least to provide accommodation for such cases as absolutely require asylum treatment, and as these may be reckoned at about 20 per cent. of the whole it follows that the present number of available beds should be at least tripled.

King Menelik as a Scientific Observer.

A member of Colonel Leontief's second expedition to Abyssinia, Dr. Theodorof, writes to last week's *Vratch* an interesting note on the use of kousso in Abyssinia as an anthelmintic, and in the course of his letter he throws light upon quite a new side of the many-sided character of King Menelik. Kousso, or *Halgenia Abyssinica*, is, it seems, not only a native product of the country but is in vast demand among the inhabitants on account of its power of expelling intestinal parasites. The first description of the plant was published by the great English traveller, Bruce, who explored the region of the sources of the Nile late in the last century. But it was only in the middle of the present century that it came into general use as an anthelmintic. As such it is a valuable drug, but its action is accompanied by unpleasant symptoms, such as nausea, vomiting, colic, and diarrhœa. The Abyssinians, however, employ it constantly, for, according to Dr. Theodorof, every person in the country is at some time or other the subject of *Tæniæ*. Possibly the male-fern does not grow in this country or its vermifuge properties are

Digitized by Google

unknown to the inhabitants; at any rate, kousso is the invariable remedy to which they resort to expel the worm. They take it in the morning, fasting, and in the form of pellets, rubbed up with other herbs. Recently, it appears, the subject engaged the attention of King Menelik, who was struck by the unpleasant complications of the action of the drug already mentioned, and he is said to have argued in the following way. The vermifuge action of kousso resides in the flowers of the plant, and probably the active principle is in the juices of the flower; consequently this active principle probably is absorbed by bees when they suck the juices, and therefore it was possible that it might still be found in the honey secreted by such bees. From theory to experiment was a short step with the king. He summoned his henchman, Takle-Georgis, and commanded him to plant a grove of kousso trees and to establish an apiary hard by, to wait until the kousso had finally ceased to blossom, and then to collect the last honey from the neighbouring hives. This was done, and as the king further argued that the active principle would probably be in more concentrated form in the honey than in the whole flower, he ordered that only a teaspoonful of the honey should be given to the selected patient in a tumbler of water. The experiment is said to have succeeded to perfection. The dose acted as a thorough vermifuge, and there were none of the unpleasant complications associated with the action of the kousso flower. The account of this interesting experiment was taken down by the writer of the letter direct from the lips of Takle-Georgis, and he adds that this method of taking kousso is now general in Abyssinia, at least among those near the king. If the story be true, and there seems no reason to doubt it, it not only shows that King Menelik is possessed of real scientific acumen, but seems to point to a new field of experimentation in practical pharmacology.

Russian Medical Conferences.

It is announced that some time next year a Russian conference of physicians will be held in St. Petersburg to deal with the subject of leprosy in Russia.

The first steps towards preparing for the Balneological Conference, already announced as to be held in Russia next year, have been taken. A preliminary commission has been formed, and at its head is Professor Pasternatzki, the President of the balneological section of the Russian National Health Society.

St. Petersburg, Oct. 11th (23rd).

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medico-legal Cases.

SEVERAL cases of medico-legal interest have been before the courts lately. The first is what is known as the "Eaglehawk murder," a case that has been going on for some time, the jury at the first trial disagreeing. Briefly the case was as follows. On Feb. 11th the wife of Charles John Hall, of Eaglehawk (Victoria), was found dead in a tub of water by her husband. Dr. Thorn was called and made, as it proved, a somewhat cursory examination of the body. An inquest was held by a police magistrate, no necropsy was made, and Dr. Thorn gave evidence that in his opinion Mrs. Hall had fainted and fallen into the tub, and being advanced in pregnancy was unable to extricate herself and was drowned. The jury returned a verdict of "Accidental death from drowning" and the body was buried. Subsequently, suspicious circumstances coming to the knowledge of the police, Hall was arrested and the body exhumed. Dr. Neild, lecturer on forensic medicine at Melbourne University, made a post-mortem examination of the body and declared that death was not due to drowning, but to suffocation, his chief reason for this opinion being the absence of water from the lungs and pleural cavities. There were also bruises on the body, and the teeth had been displaced and the nose fractured by violence applied before death. Evidence was given that Hall was improperly intimate with a barmaid named Eva Scott and on bad terms with his wife. At the trial in the criminal court the jury disagreed. At the second trial the medical evidence was the same, except that the Crown called additional experts, one of whom, Dr. Mallison, said from the description given by Dr. Neild he was not prepared to say that the signs were inconsistent with drowning. The woman Eva Scott said that she had written to Mrs. Hall informing her that Hall was the father of Scott's child, and had done so to induce Mrs. Hall to leave her husband and get a divorce. Hall had asked Scott to get poison for his wife, and had also said that if he put her head in a tub of water no one would have any suspicion. A wax model of the body of Mrs. Hall, in the position in which it was found, was made and brought into court and placed in the tub. Rigor mortis had set in when the body was found, and it was significant that one leg and thigh were extended, and the position was incompatible with the theory that she had fainted and fallen into the tub. The jury found Hall guilty of murder, and the conviction has been upheld by the executive.—Another case of more special interest to the profession is that of Searle *v.* Gurdon, just concluded in the County Court, Melbourne, before Judge Chomley and a jury. The plaintiff and his wife claimed £500 damages on the ground of alleged unskilful, improper, and negligent treatment of Mrs. Searle by E. J. Gurdon, of Brighton, medical practitioner. The defendant counter-claimed £63 10*s.* 6*d.* for medical attendance on Mrs. Searle. The evidence has not been published, but it would appear that Searle asked Dr. Gurdon to see his wife. He did so, and found that she had some endometritis and trouble in the Fallopian tubes. He advised a consultation with a specialist with a view to operation. Dr. Balls Headley was called in and performed abdominal section. It was agreed that the fee was to be 100 guineas and that Dr. Gurdon was to attend her after the operation. She recovered and went for a trip to a neighbouring colony. She continued to consult Dr. Gurdon, who said that if she was not perfectly well it might be necessary to curette, and if so he would do it without charging any special fee. She continued to improve, however, and in his opinion curetting was not necessary. The Searles then removed to another district and called in the local practitioner, Dr. R. E. Weigall. Shortly after Searle called on Dr. Gurdon and demanded that he should curette his wife free of charge. Dr. Gurdon refused, as he said he did not think it necessary, and also demanded payment of his fees. Searle then said that he did not intend to pay, that he would get Dr. Weigall to operate, and that Dr. Gurdon would have to pay the expenses incurred. Dr. Weigall operated and Searle then sued Dr. Gurdon. The jury found for the plaintiff, awarding one farthing damages and also for the defendant (Searle) on the counter claim. The judge said he took the verdict to mean that the plaintiff had no meritorious claim and that the action should not have been brought, and that the counter claim was merely a consequence of the claim. He accordingly refused to allow costs on either case. The jury added a rider that the first operation was properly performed and that professional etiquette was detrimental to the interests of patients.

Cancer Curers Committed for Manslaughter Again.

Not long ago reference was made to the trial of so-called "Professor" Davis and Dr. Spark for manslaughter in the case of a Mrs. Steele, where Davis and Spark, who are in partnership, had applied a plaster, alleged to contain arsenic, to a cancer of the breast, the case ending fatally. At an inquest concluded on Aug. 27th on the body of a Mrs. Beames the same pair were again committed for manslaughter. In this case the patient had a cancer of the tongue, and a plaster containing black sulphur and 4·6 per cent. of crystalline arsenious acid had been applied. Post mortem, no evidence of arsenical poisoning was found, the cause of death being septic pneumonia. The legal advisers of Davis and Spark maintained that the application of arsenic to cancer of the tongue was a perfectly proper proceeding, and in support of this view referred to an excerpt in the *British Medical Journal* of July 3rd of a paper by Cerny and Trunecek (*Semaine Médicale*), in which this treatment was advocated.

Sept. 14th.

DR A. M. BERGER has found in the Vatican Library (Cod. Vat., 3211) a collection of prescriptions and directions for treating various eye diseases in Michael Angelo's own handwriting, obtained probably from medical friends mainly for his own personal benefit, as it is known that the great sculptor was nearly blind before he died. Dr. Berger has published this in its original Italian with a few notes in German. It appears not to have been previously published, though it is mentioned by Pierre de Nolhac as forming an addition to Michael Angelo's manuscript poems.

Obituary.

SURGEON-GENERAL WILLIAM ROBERT CORNISH, C.I.E., F.R.C.S. ENG.

BY the death of Surgeon-General William Robert Cornish, which occurred on Oct. 19th at his residence, Corvill, Shelley-road, Worthing, one for long a prominent figure in Indian medical politics has disappeared from the scene. He was born at Corvill, Butleigh, Somersetshire, in 1828, and entered as a student at St. George's Hospital in 1850, where he distinguished himself by gaining several prizes and the William Brown Scholarship. After leaving the hospital he acted for some time as house surgeon at the Royal Sea Bathing Infirmary, Margate. He was successful in obtaining an appointment which the Court of Directors of the East India Company offered to the hospital, and proceeded to Madras in 1854 in the *Roxburgh Castle* in charge of troops. He married the youngest daughter of the late Dr. George Yeates Hunter, of Margate, by whom he had one son, the late Captain William Hunter Cornish, assistant secretary to the Government of India, who died at Simla. The loss of this son, who greatly distinguished himself and promised to have a brilliant career, no doubt greatly affected his health.

In 1858 Surgeon-General Cornish was nominated secretary to the Medical Department in Madras, and was confirmed in the appointment in 1860. Ten years later he vacated this office to become Sanitary Commissioner, and in 1871 he was directed by the Government to draw up the census report of the Madras Presidency for that year. In 1880 he was appointed surgeon-general and retired five years later, when he became honorary physician to the Queen. As the head of his department he gained the respect and affection of all ranks, both European and native. In 1877 an immense amount of labour and responsibility devolved upon him in connexion with the famine of that year. Sir Richard Temple was sent by the Government of India as Famine Delegate and advocated a ration which Surgeon-General Cornish from his professional knowledge considered inadequate for the starving natives. He contended that the Government ration doled out was insufficient to properly support life and that thereby lives were unnecessarily sacrificed. A long discussion took place between Sir Richard Temple and Surgeon-General Cornish, the latter being heartily supported by THE LANCET and the press generally. Eventually the authorities had to give way, the diet recommended by Surgeon-General Cornish was adopted, and the slow starvation ration put a stop to. Thus suffering was mitigated and further loss of life was checked. During this trying time Surgeon-General Cornish received the cordial support of the Government of Madras, represented by the Duke of Buckingham. For all this meritorious work, which resulted in saving countless lives, Surgeon-General Cornish was only rewarded with a Companionship of the Order of the Indian Empire. He was a member of the Legislative Council in Madras, showing how highly he was esteemed by his own Government. Since his retirement he busied himself as a governor of his old hospital, St. George's, and in many other useful directions, taking also an active part in the management of the Institute of Preventive Medicine. He was originally honorary [secretary] and treasurer of the College of State Medicine, and when that body was amalgamated with the British Institute of Preventive Medicine he was one of the members of its council selected to join the council of the Institute. He was a regular attendant at the council meetings and took much interest in the work, and his advice was much sought after and valued in all matters relating to the hygiene of the tropics.

THOMAS BELL FLETCHER, M.D. PARIS, F.R.C.P. LOND.

BY the death of Dr. Bell Fletcher which occurred upon Oct. 21st at Leamington, almost the oldest practitioner in these islands, has passed from our midst. Dr. Fletcher was born in Shifnal in 1806, and graduated at the University of Paris. On his return from that city he resided for some time in London, but early in the thirties he removed to Birmingham where, in 1838, he was appointed physician to the General Dispensary, which post he held for ten years, resigning in 1848 on being elected physician to the General Hospital, and this latter post he held for thirty years, when he resigned and was elected honorary consulting physician, was presented with a piece of plate and, in addition, with his portrait painted by Sir Daniel Macnee. Among other appointments he held were those of consulting physician to the South Salop Infirmary, the West Bromwich Hospital, and the Midland Counties Hospital for Women. He was also a justice of the peace for the borough of Birmingham. He was physician to the Blue-coat School and the Blind Asylum, while the foundation of the Midland Counties Asylum for Idiots at Knowle was due entirely to his efforts and those of his friend, Mr. J. H. Kimbell. In his early days he took great interest in medical education and was instrumental in founding two fully licensed schools of medicine. The first one came to an untimely end owing to the resignation of two colleagues who filled practical chairs, but the second, under the name of Sydenham College, ran a successful course for some seventeen years.

At this institution Dr. Fletcher was both principal and lecturer on Medicine, but when the scheme for its amalgamation with Queen's College was put forward he resigned both offices, being much opposed to the new idea. Eventually, however, he reconsidered his position, and accepted a seat on the council of the united colleges. In 1887 he retired altogether from practice and lived for some months in the South of France, where he partly recovered his old vigour. Returning to England he settled at Leamington and was appointed medical adviser to the visiting justices of licensed houses for the care of the insane in the county of Warwick. In May, 1887, he had an attack of cerebral hæmorrhage accompanied by hemiplegia. He was slowly recovering from this when in October of the same year he had a relapse. After this his strength very slowly but steadily declined until the day of his death. As a physician he was astute and sound in his knowledge. An instance is remembered of an able diagnosis made by him with the stethoscope at a time when it was not so universally used. The case was one of pregnancy, and Dr. Fletcher from his examination of the patient predicted twins from the presence of two fœtal hearts—a diagnosis which was subsequently verified. His opinion was greatly sought after among a large *clientèle*. In the Black Country especially an appeal from his judgment was seldom considered necessary; indeed, many looked upon his presence as a dignity to dissolution and accepted with resignation the fiat he pronounced. When "Mister" Fletcher had been called in it was thought that everything which could be done for the patient had been accomplished. What character Dr. Fletcher bore among those who knew him best is well shown by the following remarks of the *Birmingham Post* appended to the obituary notice which appeared in that journal.

"This brief sketch of Dr. Fletcher represents an energetic physician settling in a large town and attaining a high reputation by sound mental power and sheer force of character; for as a new comer he could command no local influence. His humanity, charity, and full sympathy with the poor are shown throughout the record. His educational proclivities and his constructiveness and fertility in good designs are also strongly illustrated. Dr. Brown, in his 'Horæ Subsecivæ,' has written: 'The prime qualifications of a physician may be summed up in the words capax, perspicax, sagax, efficax: *capax*—there must be room to receive and arrange and keep knowledge; *perspicax*—senses and perceptions keen, accurate, and immediate, to bring in materials from all sensible things; *sagax*—a central power of knowing what is what, and what it is worth; of choosing and rejecting; and, finally, *efficax*—the will and the way, the power to turn all the other three (capacity, perspicacity, sagacity) to account in the performance of the thing in hand, and thus rendering back to the outer world in a new and useful form what you had received from it. These are the intellectual qualities which make up the physician.' These qualities Dr. Fletcher possessed in an eminent degree, and we may add that he was honourable, high-minded, and especially practical. His theological and political views were fixed, but he was free from sectarian narrowness and controversial tendency. Hence he contracted friendships with men of most opposite convictions, and his charity was founded on the broad basis of humanity. His moral courage was equal to every emergency, and as a friend he was constant and

true. Few men have served the town more faithfully or left more enduring records of their influence and labours."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Rudolf Heidenhain, Professor of Physiology in the University of Breslau, at the age of sixty-three years. After taking his degree in 1854 he worked under Du Bois-Reymond in Berlin, and became *privat docent* in Halle. He was appointed in 1858 to succeed Dr. Purkinjes as professor of physiology and histology in Breslau. During his long tenure of this chair he published many very important researches on physiological topics, including glandular physiology, muscles and nerves, animal heat, the pneumogastric nerve, hypnotism, and an important defence of vivisection, a subject on which he felt very strongly, sending to the Prussian House of Representatives on the occasion of an anti-vivisection debate a copy of a Manual of Physiology in which he had marked with a red pencil all the facts which were only discovered by means of experiments on living animals.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the subjects indicated:—

Surgery.—A. P. Ambrose, Westminster Hospital; C. Basan, Middlesex Hospital; J. L. F. De Gannes, University College Hospital, and C. C. Poole, Guy's Hospital.

Medicine.—J. C. Bell, Guy's Hospital; P. S. Blaker, Calcutta; J. H. Chambers, Manchester; F. E. Feilden, St. Bartholomew's Hospital; T. C. Last, St. George's Hospital; C. H. Maskew, Birmingham; J. Prentice, Liverpool; and J. Spencer, Leeds.

Forensic Medicine.—P. S. Blaker, Calcutta; W. F. Chrispin, Leeds; F. E. Feilden, St. Bartholomew's Hospital; T. C. Last, St. George's Hospital; J. Prentice, Liverpool; and J. Spencer, Leeds.

Midwifery.—J. C. Bell, Guy's Hospital; P. S. Blaker, Calcutta; J. H. Chambers, Manchester; R Holt, Royal College of Surgeons, Ireland; T. C. Last, St. George's Hospital; and J. Prentice, Liverpool.

The diploma of the society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery: Messrs. A. P. Ambrose, C. Basan, P. S. Blaker, J. L. F. de Gannes, C. H. Maskew, and C. C. Poole.

UNIVERSITY OF EDINBURGH.—At the special graduation ceremonial on Oct. 23rd the following degrees were conferred:—

Degree of Doctor of Medicine.—*Roderick Murdoch Matheson, Scotland, M.B, C.M., 1893.

Degrees of Bachelor of Medicine and Master in Surgery.—Frederick William Allkin, England; Ernest Lincoln Borthwick, Australia; David Elliot Dickson, Scotland; Joseph Dominic Doherty, Australia; David Leonard Fisher, Ireland; Frank Strachey Harper, England; William Herbert Joseph Hollinshead, Australia; Neil Thomson Kerr, Scotland; Thomas Campion Lauder, Ireland; Alexander Morison Little, Scotland; John Ewart Martin, England; Sarat Kumar Mullick, India; Samuel Knight Norris, England; George Hearn Parry, England; George William Payne, Barbadoes; Thomas Bullions Shoolbread, England; William Brown Thain, Scotland; John Thomarson, England; Robert Thornton, Scotland; George Ryan Twomey, Ireland; Syed Mohamed Varis, India; and George Fyfe Waterston, Scotland.

Degrees of Bachelor of Medicine and Bachelor of Surgery—Alexander John Travers Allan, Scotland; and James Duff Scott Milln, Scotland.

* Commended for Thesis.

FOREIGN UNIVERSITY INTELLIGENCE.—*Göttingen:* Dr. August Cramer, son of the late Professor of Psychiatry in Marburg, and *privat-docent* of Mental Diseases, has been granted the title of Professor.—*Cracow:* Dr. Obalinski, Extraordinary Professor, has been promoted to the Chair of Surgery in succession to Dr. Rydygier.—*Jena:* Dr. F. Gumprecht, *privat-docent* of Internal Medicine, has been appointed Extraordinary Professor of Forensic Medicine.—*Lemberg:* Dr. H. Schramm has been recognised as *privat-docent* of Surgery.—*Pavia:* Dr. Zoia, of Parma, has been recognised as *privat-docent* of Medicine.—*Prague* (Bohemian University): Dr. Slavik has been recognised as *privat-docent* in Forensic Medicine.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the annual stated meeting of the Royal College of Physicians of Ireland, held on St. Luke's Day, Oct. 18th, 1897, the following officers were elected for the ensuing year:—President: Sir George Duffey, M.D. Dub., F.R.C.P. Irel. Vice-President: Wallace Beatty, M.D. Dub., F.R.C P. Irel. Censors: Wallace Beatty, M.D. Dub., F.R.C.P. Irel.; E. E. Lennon, F.R.C.P. Irel.; S. T. Gordon, F.R.C.P. Irel.; and R. A. Flynn, F.R.C.P. Irel. Examiners for the Licence to practise Midwifery: W. J. Smyly, M.D. T.C.D., F.R.C.P. Irel., and Andrew J. Horne, F.R.C.P. Irel. Additional Examiners, to take the place of an absent Censor or Examiner:—Medicine: A. K. F. M'Cutcheon, M.D. Dub., F.R.C.P. Irel. Medical Jurisprudence and Hygiene: H. C. Tweedy, M.D. Dub., F.R.C.P. Irel. Midwifery: Ernest H. Tweedy, F.R C.P. Irel. Additional Examiners under the Conjoint Examination Scheme:—Biology: E. MacDowel Cosgrave, M.D. Dub., F.R C.P. Irel. Chemistry and Physics: Henry T. Bewley, M.D. Dub., F.R.C.P. Irel., and Edwin Lapper, F.R.C.P. Irel. Materia Medica and Pharmacy: Ninian Falkiner, M.B. Dub., F.R.C.P. Irel.; Francis J. B. Quinlan, M.D. Dub., F.R.C.P. Irel. Physiology: John Mallet Purser, M.D. Lond., F.R.C.P. Irel. Pathology: H. T. Bewley, M.D. Dub., F.R.C.P. Irel. Medicine: John Murphy, F.R.C P. Irel.; H. C. Drury, M.D. Dub., F.R.C.P. Irel. Hygiene and Forensic Medicine: Conolly Norman, F.R.C.P. Irel. College Examiners for Conjoint Diploma in State Medicine: Meteorology and Climatology: John William Moore, M.D. Dub, F.R.C.P. Irel. Hygiene: F. J. B. Quinlan, M.D. Dub., F.R.C.P. Irel. Chemistry: Edwin Lapper, F.R.C.P. Irel. Examiners in Preliminary Education: Languages: E. J. Gwynn, F.T.C.D. Science: C. Joly, F.T.C.D. Representative on General Medical Council: Lombe Atthill, M.D., Dub., F.R.C.P. Irel. Representatives on the Committee of Management under the Conjoint Examination Scheme:—John Magee Finny, M.D. Dub., F.R.C.P. Irel.; Sir Christopher J. Nixon, M.D. R.U.I., F.R.C.P. Irel.; and James Craig, M.D. Dub., F.R.C.P. Irel. Treasurer: Lombe Atthill, M.D. Dub., F.R.C.P. Irel. Registrar: James Craig, M.D. Dub., F.R.C.P. Irel. In the evening the annual banquet of the President and Fellows was held in the College Hall. The following Fellows were present: Sir George Duffey (President), the Provost of Trinity College (Honorary Fellow), Sir John Banks, K.C.B., Dr. Gordon, Dr. Little, Dr. Finny, Dr. Walter Smith, Dr. Grimshaw, C.B, Dr. J. W. Moore, Sir C. J. Nixon, Dr. Macan, Dr. Quinlan, Dr. Smyly, Dr. Redmond, Mr. Horne, Dr. Fitzgerald, Dr. Wallace Beatty, Dr. Bewley, Mr. Molony, Dr. O'Carroll, Mr. Lapper, Mr. Norman, Dr. Falkiner, Dr. Craig, Mr. S. T. Gordon, Mr. Lennon, Dr. Drury, Mr. Murphy, Dr. Parsons, Mr. Gray, Mr. Ernest H. Tweedy, Dr. M'Cutcheon, Mr. Flynn, and Mr. Montgomery. The guests were: The Right Hon. Lord Justice Fitzgibbon, the Right Hon. W. E. Lecky, M.P., the President of the Royal College of Surgeons, Sir William Stokes, Sir William Findlater, D.L. (President of the Incorporated Law Society), Surgeon-General Preston, P.M.O., Professor Cunningham, Dr. F. W. Kidd, Dr. Purefoy, Dr. O'Keefe, Mr. J. E. Kenny, Mr. Lentaigne, Dr. A. Smith, Dr. Myles, Dr. Patteson, Mr. Usher, Dr. Lane Joynt, Rev. E. Burke, Dr. Middleton, Mr. J. M. Colles, Mr. F. B. Ormsby, Dr. Lyndon, Mr. J. J. Murphy, Mr. John Tweedy, Mr. Joly, Mr. E. Gwynn, Mr. R. Moore, Mr. George Moore, Mr. J. C. Molony, Dr. Dempsey, Dr. E. H. Taylor, Mr. Symes, Dr. Arthur Duffey, Mr. Furlong, Dr. Glenn, Mr. S. W. Wilson, Dr. S. T. Gordon, Mr. Melfort D'Alton, Mr. E. Harris-Watson, and Mr. C. W. Wilson. Mr. D'Alton, Mr. Harris-Watson, and others contributed to the enjoyment of the evening by numerous songs to which Mr. C. W. Wilson played the accompaniments.

THE NEW MEDICAL DEFENCE ASSOCIATION, LIMITED.—The ordinary general meeting of the New Medical Defence Association, Limited, was held at the offices of the society, 15, King-street, Cheapside, E.C., on Oct. 27th. The report for the year 1896-97 showed that the financial position of the society was satisfactory, the cash available on June 23rd, 1897, being £375, as compared with £312 at the corresponding period in 1896. The total administration expenses for the year 1896-97 were £22 2*s.* 2*d.* The number of members is 149, of whom, however, forty-four have placed themselves out of benefit by being in arrear with their subscriptions. The report states that the experience gained in the past shows that a subscription of 5*s.* a year will be sufficient to provide the necessary funds for pure medical defence work if the membership becomes considerable. One of the instances in which the association took action occurred in the beginning of 1897, when a member was threatened with legal proceedings for alleged malpraxis in connexion with a midwifery case. A letter was accordingly written to the person who threatened proceedings, and nothing further has been heard of the matter.

Digitized by Google

LIFEBOAT SATURDAY IN BRISTOL.—Lifeboat Saturday was held in Bristol on Oct. 23rd. This is the fourth annual effort of the kind, the first having taken place in 1894; as a result of the three previous collections £1200 have been forwarded to the institution.

THE SWANSEA MURDER CASE.—Timothy S. Jones, a medical man, who was sentenced in November last to penal servitude for life in respect of the death of a young woman at Swansea upon whom he had performed an illegal operation, has had his sentence reduced by the Home Secretary to twelve years.

THE CHELTENHAM DELANCEY HOSPITAL.—The committee of the Gloucestershire County Council in their report draw attention to the successful results of good hospital treatment as shown by the returns of the Cheltenham Delancey Hospital, where out of 263 cases (in two years) of scarlet fever, small-pox (23 cases), enteric fever, and diphtheria, not a single death had occurred.

INSURANCE FRAUD.—During the hearing of a case at Truro on Oct. 22nd Judge Granger said that the insurance policy had been fraudulently obtained by an agent and was accepted by the medical officer for the Leeds and General Friendly Society. The man insured, represented as being in good health, was an insane paralytic. The judge gave a verdict for the society, but as he thought they should have found out the case earlier costs were not allowed.

UNIVERSITY OF WALES.—The annual meeting of the court of the University of Wales was held at Cardiff on Oct. 22nd under the presidency of Dr. Isambard Owen, the Senior Deputy Chancellor. A vote of condolence was passed with Mrs. Vaughan; Dr. Owen, in proposing this, alluded to the valuable services of their ex-president in the establishment of the educational system of Wales. In the afternoon a congregation of the University was held at the Park Hall for the purpose of admitting graduates to their degrees, this being the first degree day of the Welsh University.

THE ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about $180, will be made on July 14th, 1898, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but must not have been published, and must be received by the secretary of the College on or before May 1st, 1898. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award. The Alvarenga Prize for 1897 has been awarded to Dr. Joseph Collins, of New York, for his essay entitled "Aphasia."

NORTH-EASTERN HOSPITAL FOR CHILDREN.—The committee of the North-Eastern Hospital for Children, Hackney-road, are making energetic efforts to raise funds for the erection of the additional buildings required for the completion of the original scheme. The new hospital, as designed in 1874, was intended to contain 100 beds, and the freehold of a site sufficiently large for a hospital of that size had been previously acquired, but it was found impossible to obtain sufficient money at once to carry out the plans in their entirety, and the hospital was, therefore, constructed to accommodate fifty-seven beds as at present, the erection of the remainder of the building being deferred. Last year the committee decided, after the most careful deliberation, to take steps as soon as possible to complete the hospital in pursuance of the original scheme so as to cover the whole of the land at the corner of Hackney-road and Goldsmith-row. This will, of course, involve a very heavy expenditure. Mr. Maurice Rüffer, a former member of the committee, has generously offered to head the building fund with a donation of £500 on condition that a sum of £7000 is subscribed during the year. The report for 1896 shows that 705 in-patients were treated in the course of that year; there were also 15,272 out-patients, who made 55,149 attendances.

THE ROYAL ALBERT ASYLUM FOR IDIOTS AND IMBECILES OF THE NORTHERN COUNTIES.—The annual meeting of this institution was held in the town hall of Chester on Oct. 21st, the Duke of Westminster presiding. The report stated that there were 573 patients in the institution—viz, 380 boys and 193 girls. The finances were in a sound condition, but it would be necessary to make a strong appeal for the proposed extension of the asylum and for an increased income to maintain an additional 150 patients. During the year £19,784 7*s*. had been received on maintenance account, on sustentation (endowment) account £5076 17*s*. 11*d*., and for the estate and buildings improvement account £1225 6*s*. The Earl of Derby has been appointed a trustee of the asylum in succession to the late Earl of Sefton.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual general meeting of this society was held at the Holborn Restaurant on Saturday last. Dr. E. Seaton presided. The meeting commenced with an expression of thanks being cordially voted to the retiring president, Dr. G. P. Bate, after which the report of the society for the past session was read. It stated that the society numbered 674 members, and that there were now nine branches in different parts of the kingdom. In his presidential address the chairman dealt with the relation of medical societies to the Public Health Service, urging upon members the desirability of doing their utmost to bring about the amalgamation of the various associations connected with the public health. One of the advantages of amalgamation would be an increase of influence and power in dealing with the questions of public importance with which they were concerned. He instanced the recent Maidstone epidemic as an example of the failure to recognise the full meaning and value of analysis of water-supplies. At the conclusion of his address he called attention to the fact that it was the fiftieth anniversary of the appointment of the first medical officer of health in England—namely, Dr. Duncan, of Liverpool—and he expressed the hope that the society would commemorate the event by a union of the societies over which the interests of public health administration were at present scattered far too widely.

UNIVERSITY OF CAMBRIDGE.—The election of a Professor of Pathology will take place on Saturday, Nov. 6th, at Downing College Lodge. The electors are Dr. Bradbury, Dr. Gaskell, Professor Foster, Dr. J. F. Payne, Dr. Allbutt, Sir J. Paget, Dr. D. MacAlister, and Dr. Latham. Mr. J. Graham Kerr, B.A., of Christ's College, has been appointed Demonstrator in Animal Morphology, in the place of Mr. E. W. Macbride, lately appointed Professor of Zoology in McGill University, Montreal. At the congregation on Oct. 14th the degree of Doctor of Medicine was conferred on A. J. H. Saw, M.B., B.A., Trinity College; W. J. Harris, M.B., B.A., Caius College; and F. M. Rowland, M.B., B.A., Caius College. The degrees of M.B. and B.C. were conferred on E. A. Houseman, B.A., Clare College, and A. M. Barraclough, B.A., Christ's College.—Professor Wiltshire has presented to the Mineralogical Museum his large and precious collection of minerals; it includes a number of beautiful specimens of high scientific value. The zoological museum has also been enriched by the addition of a fine collection of polyzoa presented by Miss E. C. Jelly, and of the skeleton of a fine elephant seal the gift of Sir W. L. Buller. The Registrary announces that the First and Second Examinations for M.B. will begin on Dec. 13th; that Parts I. and II. of the Third Examination will begin on Dec. 14th, and that the examination for the M.C. degree will begin on Dec. 17th. The names of candidates should be sent in by Nov. 30th. The following registered practitioners have been successful in the recent examination for the diploma in Public Health: A. J. Adkins, A. Balfour, P. L. Benson, W. M. Brown, G. H. Cock, W. S. Cook, R. Dick, C. R. Elliott, R. A. Farrar, S. Gillies, C. H. Graham, M. Kelly, A. J. Laird, C. F. Lillie, A. T. McConkey, R. J. Millard, T. B. Stedman, and J. R. Watson. On Oct. 21st the number of freshmen matriculated was 872, an increase of about 40 on last year's figures. The returns as to the number of medical students are not yet complete. The following have been appointed examiners for the first and second M.B. examinations:—Physics: Mr. Wilberforce and Mr. Capstick; Chemistry: Mr. Bell and Mr. Ruhemann; Biology: Mr. Lister and Mr. Seward; Pharmaceutica Chemistry: Mr. Ivatt and Mr. Adie; Anatomy: Dr

Digitized by Google

Barclay-Smith and Professor A. M. Paterson; Physiology: Dr. Snore and Dr. A. D. Waller.

MR. THOMAS WEBB FOWLER, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., has been nominated for the Mayoralty of Coventry.

SUPERANNUATION ALLOWANCE. — Mr. Richard Turner, M.R.C.S. Eng., late medical officer of the Lewes Prison, has been awarded by the Treasury a retiring pension of £138 per annum.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, MARYLEBONE-ROAD. N.W.—The Committee of Management of Queen Charlotte's Lying-in Hospital, Marylebone-road, have received a donation of £1000 from Mr. Henry L. Raphael, to name a bed in perpetuity in memory of the late Mrs. H. L. Raphael.

ST. LUKE'S DAY.—Under the ægis of the Guild of St. Luke a service was held in St. Paul's Cathedral on Oct. 19th. The service was the ordinary Evensong, the sermon being preached by the Archbishop of York from the text, "Himself took our infirmities and bore our sufferings," with the object of showing the inter-relation between the medical and clerical callings.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—A meeting of the governors of this college was held on Oct. 20th under the presidency of Lord Tredegar. Lord Windsor and Dr. W. T. Edwards were re-elected vice-presidents and Mr. L. Tylor was reappointed treasurer. The principal stated that the building fund of the college amounted to £39 877, and he anticipated that the total would reach £40,000 before the end of the year.

MEDICAL MAGISTRATES. — Mr. F. Bagshawe, M.D. Cantab., F.R.C.P. Lond., of St. Leonard's-on-Sea, has been placed on the Commission of the Peace. Mr. Thomas B. Belgrave, M.D. Edin., M.R.C.S. Eng., of Silverton, New South Wales, Mr. H. I. Tresidder, L.R.C.P. Lond., M.R.C.S. Eng., of Dubbo, New South Wales, Mr. George E. Rennie, M.D. Lond., M.R.C.S. Eng., of Sydney, New South Wales, and Mr. George L. L. Lawson, M.R.C.P. Edin., M.R.C.S. Eng., of Yalgoo, Western Australia, have been appointed Justices of the Peace.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—The quarterly meeting of the Devonshire Hospital and Buxton Bath Charity was held in the hospital buildings at Buxton on Oct. 2nd, Mr. Henry Shaw, J.P., being in the chair. The report stated that 250 patients were on the books at the end of June and that 1044 were admitted during the three months ended Sept. 30th. Of this number 951 were discharged as "improved," 68 as "no better," 4 at their own wish, 2 as "unfit cases," 2 were made out-patients, 1 died, and 266 remained on the books.

THE Governors of the Royal Kepier Grammer School, Houghton-le-Spring, have awarded the Heath Medical Scholarship to Thomas Rowell, a pupil of the school. This scholarship, which is tenable for three years at the University of Durham College of Medicine, Newcastle-on-Tyne, was founded a few years ago at the school in memory of the late George Yeoman Heath, M.B. Lond., F.R.C.S. Eng., Professor of Surgery in the University of Durham. The new scholar is a son of Mr. Rowell, a practitioner of Houghton-le-Spring.

THE NEW INFECTIOUS DISEASES HOSPITAL FOR GLOUCESTER.—Last week the Mayor of Gloucester, accompanied by various members of the corporation, laid the foundation stone of the new infectious diseases hospital for Gloucester. The site is what is known as Vineyards Hill, Over, about two miles from the city, and is an excellent position with a southern exposure. The position of the wards has already been set out in such a manner as to allow of future extension if necessary. The plans provide for two pavilions for fever cases, each containing six beds for males and six for females, in addition to which there will be an observation ward containing four beds for males and four for females. The total number of beds will therefore be thirty-two. The connexion between the pavilions and the administrative block will be by covered ways with open sides, and the roadways will enable the ambulance to approach the wards separately. It is proposed that the buildings shall be of red brick, and the whole of the pavilion and administrative block will be placed on concrete with through ventilation beneath the floors. The architects are Mr. F. Waller and Mr. H. Medland, both of Gloucester. Temporary wards of corrugated iron have been placed upon the site for the reception of the patients during the erection of the permanent buildings.

PRESENTATIONS TO MEDICAL MEN.—On Oct. 21st a numerous meeting of the Leeds police force assembled at the town-hall to receive from the Lord Mayor of the city the certificates gained by them in connexion with the St. John Ambulance Association; at the same time he presented, on behalf of the men, a purse of gold to Mr. G. H. Heald, L.R.C.P. Edin., M.R.C.S. Eng., their instructing surgeon on First Aid.—At a meeting of the aldermen and residents, held in the town-hall, Dubbo, New South Wales, the Mayor presiding, Mr. Edward J. Haynes, L.R.C.P. Lond., M.R.C.S. Eng., was presented with a farewell address on his leaving the town.—Mr. Charles J. Whitby, B.A., M.D. Cantab., who has been for the past seven years resident physician at the Limpley Stoke Hydropathic Establishment, near Bath, has been presented with a purse of gold by his friends and patients upon the occasion of his receiving another appointment.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

GLANDULEN TABLETS.

MESSRS. THOMAS CHRISTY AND CO., 25, Lime-street, E.C., have forwarded to us samples of glandulen, an animal product prepared in tablet form for medicinal use by Dr. Hofmann, manufacturing chemist, Meerane, Saxony. Glandulen is obtained from the bronchial glands of freshly-killed sheep. Having been washed with alcohol, freed from fat, and dried in vacuo at a low temperature, the glands are reduced to powder, to which sugar of milk is added in such proportion that when compressed into tablets weighing 0·25 gramme (3¾ grains), each tablet is equivalent to 0·25 gramme (3¾ grains) of the fresh glandular substance. One tablet is given three times a day at first, the dose being gradually increased to five tablets three times daily. Glandulen is stated to have been tried in cases of tuberculosis of the lungs.

MEDICAL BIOGRAPHIES: A QUERY.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers tell me where to obtain the biographies of Dr. John Fothergill, Boerhaave by Johnson Abercrombie, and Dr. Stokes, mentioned in the Students' Number of THE LANCET of September, 1896, who is the publisher, and what is the price? I am, Sirs, yours faithfully,

Oct. 14th, 1897. R. W. H.

*** A good account of Dr. John Fothergill, read before the Medical Society of London in 1782, will be found in the third volume of his works, by John Coakley Lettsom. "The Life of Boerhaave," by Dr. Johnson, will be found in Johnson's works. A short account of Dr. Stokes, of Dublin, is given in "Eminent Doctors," by G. J. Bellamy. The life of Abercrombie is also shortly given in encyclopædias.—ED. L.

MEDICAL DICHOTOMY.

IN an article on this thorny subject which appears in *Le Courrier Médical* the writer, Dr. Cézilly, quotes Dr. Huguenin to the following effect: "1. When a medical practitioner is doubtful about his diagnosis, prognosis, or treatment, or else merely wishes to cover his responsibility, he calls in the consultant of his choice, who may be professor, deputy professor, hospital physician, or even a general practitioner with no other distinction than his knowledge and uprightness. What should he demand by way of honorarium? Twice his usual fee, provided that the amount is in no case less than ten francs. 2. A capricious patient having little confidence in his own medical man, or else desirous of ascertaining whether his cure can be accelerated, calls in a consultant and, as it were, imposes him upon the practitioner in attendance. What fee should the latter receive? A quarter of the amount given to the consultant. 3. Assistance at an operation of any description, but without actual participation in the operative procedure, should be recompensed as follows: Fifty francs if the patient belong to the middle classes, one hundred francs if he be wealthy. 4. When the assistant has taken part in the operation the operating surgeon alone is competent to decide what his remuneration should be, and it is also the duty of this gentleman, not only to apply for the money, but also to indicate its destination. The sum in question should, however, never be less than 150 francs."

COMPETITION IN THE COLONIES.

MR. EDITOR. Gisborne, Sept. 4/97.

DEAR SIR,—I hope you will excuse me for taking the liberty of sending you the enclosed I do not know if such cases comes under your notice I think that different of the Dr's in this Coloney does not understand such cases and it is not in my line to spend time with them being a long way from being a medical man I have only treated a very fue cases.

If you see nothing in the enclosed please comit it to the Wast paper Baket and oblidge—You most obedent servant,

JAMES ROSIE.

Care of Mr. Cecil Lewis, Produce Merchant,
Gisborne, New Zealand.

[ENCLOSURE.]

To the Editor of THE LANCET.

The young Ladie was a little over 16 years her trouble began with felling lonesome (Languid) and soon after a weakness in her limbs she did not feel inclined to do any thing But as the weather was very warm they did not think much about it as she had no pain but when her monthlys stoped the Dr then advised her to take Sea trip they so and got other medical advise he gave her a Tonic and expected she would soon be well short after returnig home they saw she was losing Flesh as well as her appetite the Dr was called he thought he could do some thing for her now as the weather was cool But her skine (Flesh) began to feel cold and she tooked pail yet no pain she soon got so weak that she had to take to bed she soon got so Bad that nothing would stay on her stomach. When I saw her for the first time she scarcly could move her limbs and was just Skine and Bones and felt cold yet she had only a little pain across the fore head. In a fue days under my treatment she could move her limbs and a fue days more we got her out of Bed she is now as well as ever she was. From the first appearne of her trouble to the time she was out of Bed would be over six months.

J. R.

*** We see a great deal in the enclosure, and so have not "comited" it to the "Wast paper Baket." We see that a person "a long way from being a medical man," and also from being a commonly educated man, has calmly taken upon himself medical duties. Mr. Rosie is recommended to understand that if he had had under his care a case which had ended fatally through lack of medical aid, instead of a case the natural and everyday termination of which was perfect recovery, there is no moral reason why he should not be hanged.—ED. L.

"THE TREATMENT OF CORNS."

To the Editors of THE LANCET.

SIRS,—A layman has communicated to me a little "tip" concerning corn-plasters which may prove of service to your correspondent, Mr. J. T. Jones. "Some ten years ago," he writes, "I was a martyr to corns. The putting on of a boot was worse than I imagine the rack would have been. I was advised to try corn-plasters but not to 'apply 'em as you buy 'em,' because that, I was told, might aggravate my trouble. I was instructed to cut the plaster in two across the centre (see diagram) and then to apply the two sections round the base of the corn. This method afforded me relief at once, and in six months I had got rid of corns which had previously crippled me."

It seems to me that a corn-plaster used in this way would often gain in value, as the two sections can be fitted round the base of the corn accurately and tightly in a way that is impossible when dealing with a ring of a fixed circumference. I am, Sirs, yours faithfully,

Oct. 25th, 1897. M.D., &c.

PLAGUE SPAWN.

AMONG the many evils which accompany plagues—we use the word in the sense of epidemic disease generally—is the host of lying scoundrels to which they give birth, who trade upon people's fears, and under the cloak of religion line their pockets with the gold of their dupes. There were plenty of them in the great plague of London, of whom many, we are glad to say, died therefrom. They issued handbills and held meetings, but we doubt whether any such infamous bill as the one here reprinted has ever been issued before.

NOTICE.

SAD FEVER CALAMITY IN MAIDSTONE.

'LIFE OR DEATH.'

On SUNDAY NEXT, Oct. 17th, 1897,

TWO PUBLIC MEETINGS

WILL BE HELD IN THE

Alexandra Hall, Tonbridge Rd., Maidstone,

(By kind permission of the Christian Friend), when

PROFESSOR HOBBS

(Promoter of Electric Communication between Light Ships, Light Houses, and the Shore to Save Life. Also the Mansion House Meeting in London in 1881),

Will address the Audience upon the Sad Fever Calamity to 1670 persons and Awful Deaths of 91, and will prove that the progress of Fever can be arrested within a very short time, the Patient smiling, sleeping, and soon eating. Letters from the Princess of Wales and Lord Rosebery; also Portraits and Letters of Lady Rosebery, and a patient cured at 84 years of age, who died at 92; the gardener of the late Archbishop of Canterbury (his Daughter cured of Consumption and Dropsy); a Patient who was covered with Scarlet Fever in the morning, and running in the bedroom in the evening, the next morning down to breakfast, etc., etc.; "also a Patient cured of Cancer," and one treated for nine Cancers.

A letter will be read by the Chairman from the late John Smedly, who had nearly 50,000 patients treated at his Home, and not one "Fatal Case" of Fever during his life, and not one case transferred to any Ignorant Doctor, Brewer, Publican, Wine or Spirit Merchant, or Licensed Grocer to be cured by cursed alcohol," and who believed with the Professor that the late beloved Prince Consort could have been relieved within an hour.

The Professor will give the particulars of a case of Fever stated to be of seven weeks' standing, who was pronounced beyond hope by the M.D. Two others were requested to see her insensible, grating her teeth, and moaning. Within 15 minutes the brain was relieved of Fever, and the patient soon asleep.

The Correspondence will be produced between the Asylums' Board, London, and Mr. Hobbs in favour of the use of six Beds in the Hospital, London, being allowed him for him to prove to 50 M.D.'s that he can relieve Fever Cases in 15 minutes if taken early. Fifty seats will be reserved for the Doctors and Nurses, who are earnestly and affectionately invited to attend, that they may learn how to prevent Pains, Suffering, and Death.

The Chair to be taken at 3 o'clock prompt, and 8.15 o'clock, by

TWO PHILANTHROPISTS OF MAIDSTONE.

Hundreds of Testimonials, Letters, &c., will be produced, received from supposed dying Patients, who are by now well, *after being* treated *Free* of charge.

A Collection will be made after each Meeting to defray Expenses, and provide a Free National Home (advocated to be built by an eminent London Physician, after proving the great success attending Mr. H.'s treatment of Mild Hydrophy and Medical Botany for 40 years) for the suffering.

The Clergymen and Ministers of the Town will oblige by announcing the Meetings from the various Pulpits on the Morning of the 17th of October, 1897.

The ignorance, the lying, and the nauseating infusion of spurious religion (who is "the Christian friend"?) make this bill a specially bad specimen of its class when we consider the circumstances under which it was issued. We should much like to know if any of the clergymen of the town were weak enough to give notice of the meetings from the pulpit, and if so whether the circumstance has come under the notice of His Grace of Canterbury. If so they will have a bad quarter of an hour, for if ever there was a man who has a hatred of humbug it is the present holder of the See of Canterbury. In that admirable little work "Loimographia" occurs the following sentence: "If God had not made venomous and hurtful creatures as well as others man would have wanted objects whereon to exercise his reason and prudence." Herein we have an explanation of the existence of persons like "Professor" Hobbs.

Mr. Arthur Field is thanked for his communication.

THE SOLUBILITY OF THE HUMAN BODY.

THE police authorities in Chicago have recently undertaken a series of experiments with a view to determining the innocence or guilt of a wealthy sausage maker, named Adolphus Luetgert, who is accused of having killed his wife and made away with her body by dissolution in a vessel containing a corrosive liquid. One of the experiments, which is said to have been perfectly successful, was performed in the following manner. A corpse having been procured it was stripped entirely naked and placed in a vat filled with a strong solution of caustic potash. After two hours the cover was removed, when it was found that, with the exception of a few fragments of bone and a small quantity of viscid matter having the consistency and appearance of molasses, the body had completely disappeared. In consequence of this conclusive demonstration it is held as established that Luetgert could have got rid of his wife's remains in a similar way, although before the experiment was tried several experts had declared that the thing was impossible. It seems that the only link that was wanting in the chain of evidence against the sausage maker has now been supplied, and according to the district attorney there is every probability of his conviction for murder.

Enquirer.—The circulars are most objectionable, but we doubt if the General Medical Council would consider their dissemination to constitute "infamous conduct in a professional respect."

"A FURTHER IMPROVEMENT IN DISINFECTION BY STEAM."

To the Editors of THE LANCET.

SIRS,—We observe in THE LANCET of the 23rd inst., p. 1058, notes on "A Further Improvement in Disinfection by Steam." The alleged improvement appears to consist in creating a vacuum in the disinfecting chamber by means of a steam jet, and we beg to point out that this is the apparatus known in this country as Alliott and Paton's Patent. We enclose our circular, No. 228, generally illustrating and describing this machine, which has been in use in this country for some years past and is thoroughly well known; it has, in fact, been illustrated and advertised in your columns. We also enclose circular 250 "Instructions for Working," which is, you will see, so far as it goes, identical with that described by you, but the Alliott and Paton's patent machine is in many respects more complete and perfect than the American apparatus you describe. We also enclose circular 256, being a list of places where this Alliott and Paton's patent disinfector has been adopted, from which you will see that it is well known and widely used not only throughout the United Kingdom and Ireland, but in the colonies and foreign countries; and as there are several of these machines at work in Canada it is not unlikely that the American machine you speak of may have been simply copied from one of these. We shall feel obliged if you will, in your next issue, be good enough to correct the statement that the American apparatus described by you is "a further improvement in disinfection by steam," being already widely known and largely used in the Alliott and Paton's patent machines of our manufacture. We are, Sirs, yours truly,

p.pro. MANLOVE ALLIOTT AND CO., Limited.
Nottingham, Oct. 25th, 1897. THOS. CANTRELL, Secretary.

A PROSECUTION UNDER THE NOTIFICATION OF DISEASES ACT.

DR. THOMAS BUCHANAN DUNN was summoned on Wednesday by the sanitary authority of St. Matthew, Bethnal-green, under the Public Health Act, for not having notified to the medical officer of the parish two cases of scarlet fever under his care. No appearance was made for the defence, and a penalty of 20*s.* in each case, with 14*s.* costs was imposed.

Veritas.—The last Calendar is dated July 29th, 1897, and has been issued some weeks. The price is 1*s.*, and the publishers are Messrs. Taylor and Francis, Red Lion-court, Fleet-street, E.C.

VILLAGE NURSES.

A RURAL Nurses' Association for Bedfordshire was recently started at a meeting presided over by the Duchess of Bedford, and in reference to this undertaking Mr. Edwin Ransom, J.P., of Bedford, has written a judicious letter to the *Bedfordshire Standard* of Oct. 8th on the subject of the relations existing between medical practitioners and village nurses. He says: "A village nurse is apt to be asked and even expected to do things which common-sense and a moment's reflection should leave to a doctor. Accident and sudden illness have a claim for 'first aid' on a nurse or anyone else who can render it—until the legally responsible practitioner arrives. At the same time it is too common in some places, and not only among the poorest people, for the nurse to be called in the first instance and thus for her to be sending for the doctor when the doctor ought to be sending for the nurse.'

THE SALARY OF A MEDICAL OFFICER OF HEALTH.

The *Local Government Chronicle* writes:—

"The Local Government Board are not satisfied with the salary the Lowestoft Corporation are paying to their medical officer, Dr. O'Connor, and that gentleman is perfectly in agreement with the Board. The doctor states that his hours of attendance average between eight and nine a day. Out of the £100 a year he receives as medical officer he is this year expending £30 on bacteriological and chemical apparatus, and the £30 he receives as superintendent of the Infectious Diseases Hospital has not paid for the medicines he has supplied. Out of the £90 he gets as net salary he has to pay £63 in rent. The chairman of the corporation declined to make any recommendation on the subject, but the council decided to consider next month the advisableness of giving the doctor a gratuity."

We are not surprised to learn that both the department and the medical officer of health in question find the remuneration scanty.

G. S. P. will find the information which he requires in the last "Student's Number" of THE LANCET, which was published on Aug. 21st, 1897.

"SCARLET FEVER AND THE PRACTICE OF MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—With reference to your note in THE LANCET of Oct. 23rd under the above heading will you allow me to state: I had not been engaged to attend Mrs. Munday in her confinement. Mr. Bilham not only "at first" but still thinks the case was not scarlet fever. Mr. Bilham had not seen me for two days previous to his attendance on Mrs. Munday, and all other confinements attended by him while acting for me did well. Directions as to isolation were given by the medical man who was attending me and were carried out to his satisfaction. No member of my household was infected. Mr. Bilham before leaving the surgery in the morning, and when attending a confinement, disinfected his hands by rinsing them in bichloride solution. It is most imperative when attending midwifery cases to avoid unnecessary contact with persons suffering from contagious complaints and to use efficient means of disinfection, but is it not impracticable for a medical man in general practice to cease attendance on or avoid contact with contagious cases? I am, Sirs, yours faithfully,

Oct. 27th, 1897. E. T. WHITEHEAD.

*** We pointed out in our note that it is not possible for the general practitioner to avoid contact with contagious diseases because he has midwifery cases on his list. He must trust to disinfection and scrupulous care, and that these are sufficient to obviate public risk is proved to the hilt by the rarity of the spread of disease *vid* the medical man. After reading Mr. Whitehead's letter most medical men will agree with us that it is unlikely that Mr. Bilham conveyed the infection to the patient.—ED. L.

"TOE POST" SHOES.

To the Editors of THE LANCET.

SIRS,—Would any of your correspondents inform me of the maker of "Toe Post" shoes for the cure of bunions?

I am, Sirs, yours faithfully,

Oct 12th, 1897. O. TRAFFORD OWEN, M.B. Edin.

*** The makers of "Toe Post" shoes are Messrs. Holden Bros. 223½, Regent-street, W.—ED. L.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Midland Counties Express, Lincoln Gazette, Luton Reporter, Brighton Herald, Bournmouth Observer, Newark Advertiser, Grimsby Chronicle, Hereford Times, Southern Echo, Lowestoft Standard, Leicester Post, Times of India, Pioneer Mail, Batley Reporter, Burton Chronicle, Devon County Standard, Rugby Advertiser, Liverpool Daily Post, Kent Messenger, Builder, Architect, Staffordshire Chronicle, Bedford Times, Wilts Standard, Le Figaro, Birmingham Post, Dundee Advertiser, Yorkshire Post, Glasgow Herald, Manchester Guardian, Western Morning News, Newcastle Chronicle, Leeds Mercury, Scotsman, Mirfield Reporter, Yarmouth Independent, Catholic Times, Cromer Post, Northampton Herald, East Anglian Daily Times, Ampthill News, Bristol Mercury, Dunstable Advertiser, North Wilts Herald, Cheltenham Mercury, Derbyshire Advertiser, Newton Observer, Hampshire Chronicle, Brighton Gazette, Kidderminster Shuttle, Evesham Journal, Carlisle Journal, Sanitary Record, Mining Journal, Reading Mercury, Hertfordshire Mercury, Local Government Chronicle, Kerry Sentinel, City Press, Middlesex Hospital Journal, Weekly Free Press and Aberdeen Herald, Coventry Mercury, Australasian Medical Gazette, Essex Telegraph, Surrey Advertiser, Bolton Daily Chronicle, Local Government Journal, Kerry Weekly Reporter, Eastern Daily Press, Daily Gleaner (Kingston, Jamaica), West Middlesex Herald, Brighouse News, &c., &c.**

TRADE MARK

'Tabloid' BRAND

Medicinal Syrups.

'Tabloid' Hypophosphites Compound. 1-1/2 gr. and 3 gr.

Equivalent respectively to ½ or 1 dram of standard Compound Syrup of Hypophosphites (containing 1/64 gr. of Hypophosphite of Strychnine to each dram.)

1-1/2 gr., in bottles of 25 and 100, 9d. and 1s. 6d. per bottle.
3 gr., in bottles of 25 and 100, 10d. and 2s. per bottle.

'Tabloid' Chemical Food (Phosphates Compound). 2-1/2 gr. and 5 gr.

Equivalent respectively to ½ or 1 dram of standard Compound Syrup of Phosphates.

2-1/2 gr., in bottles of 25 and 100, 6d. and 1s. 3d. per bottle.
5 gr., in bottles of 25 and 100, 9d. and 1s. 8d. per bottle.

'Tabloid' Easton Syrup.

1/2 dr., in bottles of 25 and 100, 9d. and 1s. 6d. per bottle.
1 dr., in bottles of 25 and 100, 10d. and 2s. per bottle.

ALL SUGAR COATED.

A group of 'Tabloid' products which includes 'Tabloid' Hypophosphites Compound, 'Tabloid' Chemical Food (Phosphates Compound), and 'Tabloid' Easton Syrup.

The syrups of the hypophosphites and the phosphates as well as Easton Syrup are frequently unstable and often objectionable on the score of taste and bulkiness. The 'Tabloid' Medicinal Syrups are permanent and pleasant to take. Supplies can be carried in the pocket and doses taken regularly during the usual daily routine of work.

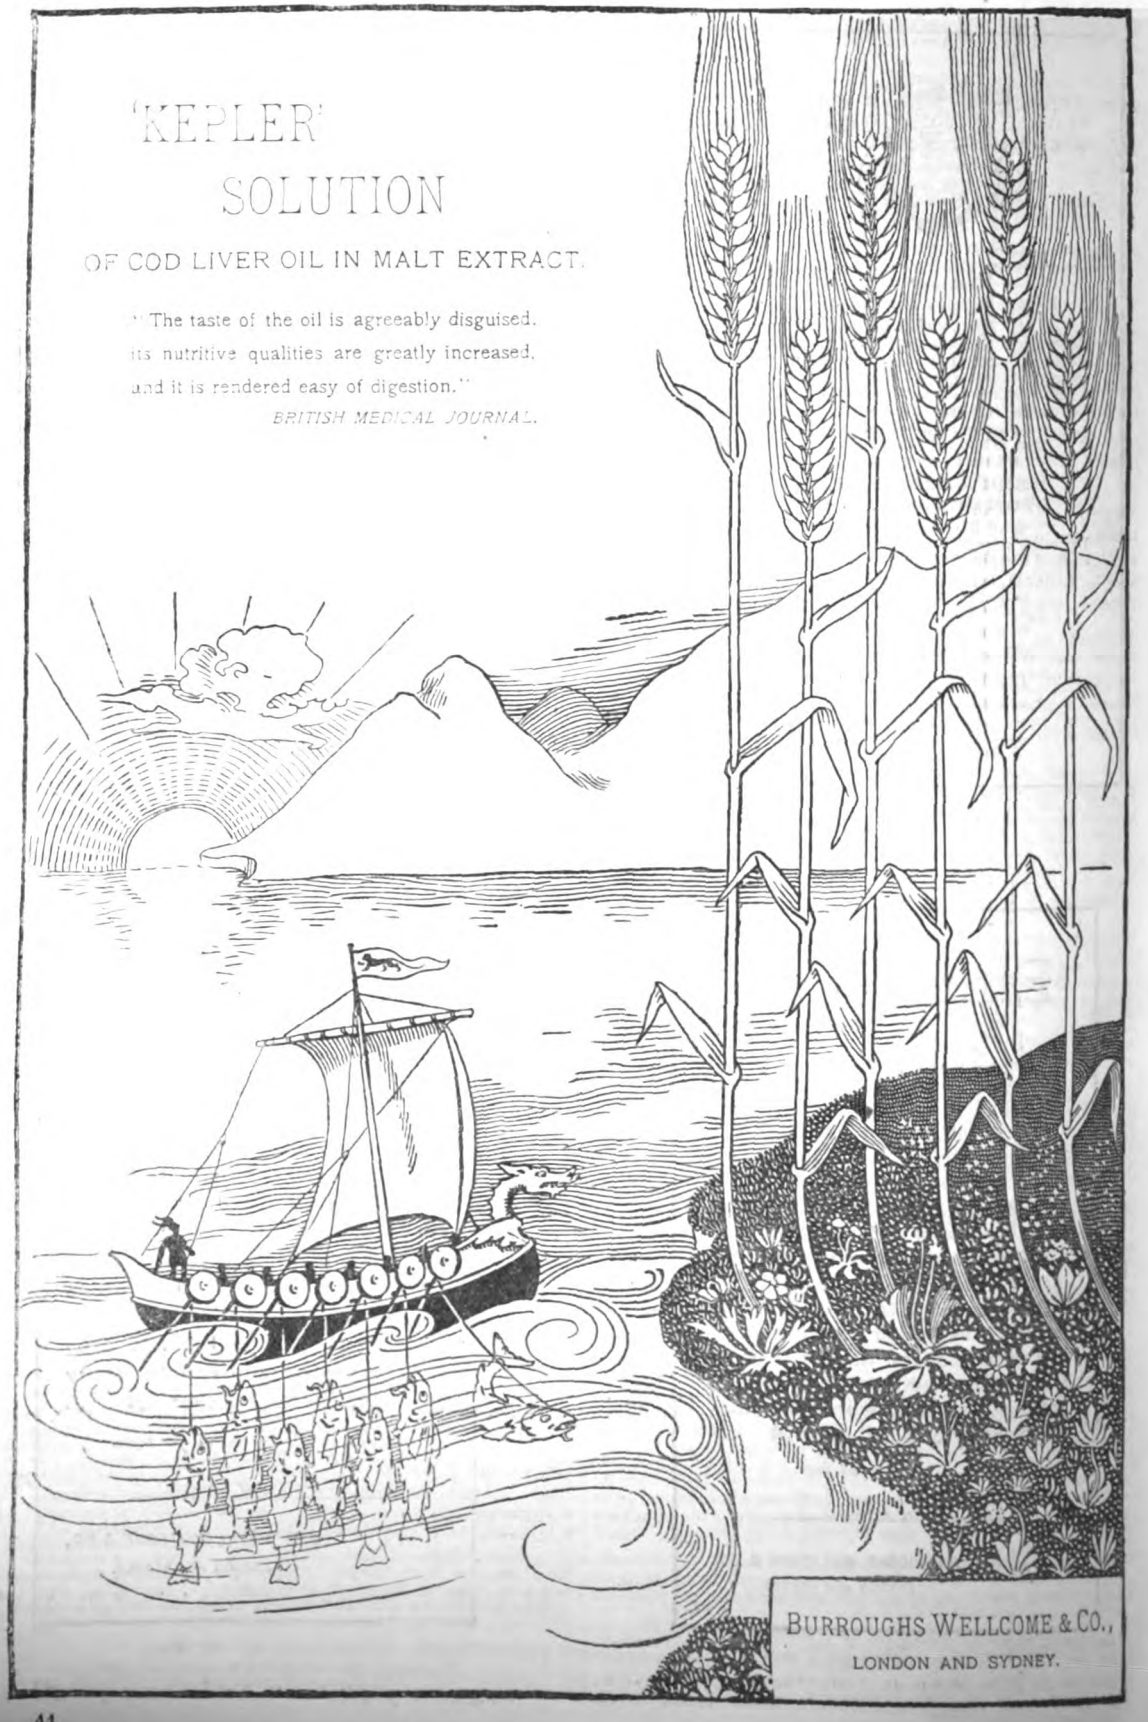
LONDON and SYDNEY.

'Saxin'



(Trade Mark.)

Is a delicious sweetening agent, about 600 times sweeter than sugar, and has been aptly termed 'the sweetest thing on earth.' 'Saxin' is indicated in diabetes, gout, glycosuria, obesity, etc., because it undergoes no change in the system. A 1/4 gr. of 'Saxin' is equivalent to one lump of best loaf sugar. A small bottle containing 100 or 200 can be easily carried in the vest pocket.

Supplied at 7d. and 1s. 1d per bottle.

The Bradshaw Lecture

ON

PROGNOSIS IN HEART DISEASE.

Delivered before the Royal College of Physicians of London on Nov. 4th, 1897,

BY E. MARKHAM SKERRITT, M.D., F.R.C.P. LOND.,

PROFESSOR OF MEDICINE IN UNIVERSITY COLLEGE, BRISTOL; SENIOR PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL; FELLOW OF UNIVERSITY COLLEGE, LONDON.

MR. PRESIDENT AND GENTLEMEN,—It is probably the wont of those upon whom from time to time devolves the responsibility of delivering the lectures associated with this College to select for their discourse matters to which they have devoted special consideration, or which are to them invested with peculiar interest. Therefore when you, Sir, did me the altogether unexpected honour to invite me to deliver the Bradshaw Lecture for the present year it seemed to me that I could but discharge the important duty with which I was entrusted by treating of some subject which had been in the forefront of my observation and thought during my active professional life, and my choice fell upon a theme which has also engaged the attention of those who have spoken with an authority to which it is not for me to aspire—one, however, which in its importance is always fresh, and is constantly present to the practical physician, offering for his solution ever-varying problems.

The Father of Medicine has said, "The art of physic is of great extent, life short, opportunity slippery, experience fallacious, and judgment difficult." Still but too true of our art as a whole, this applies with equal force to one at least of its branches. Who is there that of his own experience cannot say of prognosis in disease that "opportunity is slippery, experience fallacious, and judgment difficult"? And assuredly a full share of difficulty and fallacy surrounds the subject which I have chosen for this lecture, for although in none of the ills which flesh is heir to is a knowledge of what the future has in store of greater moment than in heart disease, yet in few things is the possible margin of error so wide. It is not practicable within the time at my disposal to enter into a detailed consideration of the prognosis of heart disease in its various forms. Nor should I here venture to trespass upon ground which has before been occupied by those with whom I could not presume to compete. I propose rather to treat the subject from a general point of view and to discuss it in certain aspects and phases, having especial regard to the origin and nature of some of the uncertainties by which it is surrounded.

The following factors enter into prognosis in heart disease. First, an accurate estimate of the nature and extent of the changes which have occurred in a given case—that is to say, a complete diagnosis. Next, a knowledge of its past history with special reference to the causation of the cardiac trouble and the length of time that it has existed. Thirdly, an acquaintance with the course that may be run by a lesion such as is present. And lastly, a due weighing of the special features of the case in question.

There is no need to argue at length the dependence of prognosis upon diagnosis. If diagnosis is imperfect or faulty or totally wrong prognosis will be correspondingly erroneous. The foundation of prognosis is an accurate appreciation of the changes produced by disease and of the pathological nature of the processes concerned—a knowledge, that is to say, not only of what alterations have occurred in shape or size or structure or function of an organ or part, but of how they have been caused, and what is the ultimate history of the morbid agencies to which they are due. Where the heart is concerned error in prognosis may arise in connexion with either of these two factors; on the one hand, through mistake as to the actual physical condition of the organ; on the other hand, owing to failure to realise what will be the resultant of the various forces which are rightly recognised as at work. And difficulty in these two directions tends rather to lie towards the extremes of age. In early life the discovery of the lesion is usually easy, but there are wide possibilities as to its future course, while with advancing years comes the time of degeneration, which in its gravest forms often cannot with certainty be recognised. For youth is the period of acute inflammations—of pericarditis and endocarditis—which are commonly discovered with ease by the skilled observer; but no wisdom will avail to surely foretell the future whilst acute endocarditis is running its course. Whether when the inflammation subsides the roughened valve will be smoothed and that unusual event occur, the disappearance of the murmur of acute endocarditis; or the morbid sound persist, but based on so little actual valve change as to remain a murmur and nothing more; or whether the lesion is destined to work havoc with the heart and bring life to a speedy close,—all this is beyond the reach of human foresight. Diagnosis is simple, definite prognosis impossible. Towards the other end of life the opposite tends to obtain. Degeneration has no distinctive physical signs; and it often cannot be said with certainty whether the halting action of the organ is due to change which is organic and will remain or comes from simple and remediable weakness. Upon the view that is taken of the nature of the affection depends the prognosis that is given; on the one hand, a grave forecast of increasingly impending evil; on the other hand, it may be, the prospect of restored powers and lengthened years. But perchance the promise of peace and length of days is made to the man whose heart is changing into fat, while the sword is hung over one whose only need is nourishment and rest.

It is important to recognise what is the position of physical signs in heart disease—how far they can be relied upon as evidence of the nature and extent of existing morbid changes and of their tendencies. Speaking of valvular disease Markham[1] says: "A too curious investigation of physical signs is apt here, as in the case of all other diseases where physical diagnosis is concerned, to make the observer less attentive to the general signs and symptoms than their real importance demands." And Wardrop[2] expresses his views in still stronger terms: "How many examples of erroneous prognosis do we not all meet with? And I am convinced that nothing has contributed more to extend this humiliating catalogue than the introduction of auscultation." It is needless to say that the stethoscope does not merit such sweeping condemnation. And yet it cannot be denied that many of the errors made in the prognosis of heart disease—and especially of valvular lesions—arise from too narrow a reliance upon its indications. The stethoscope will discover the "physical sign proper," the murmurs, and therefore decide to which of the various classes of valvular defect any case belongs, and by placing it in this category or in that determine what are the usual tendencies of the affection. But here its function ends; beyond this it does no indicate what is in store for the particular patient. It is well known that the quality of a murmur is no guide to the amount of valvular mischief which exists. For while the loudest murmur may remain for many years with quite unimportant results the effects of a valvular lesion may sometimes be too grave for the production of a murmur at all. But we cannot adopt Latham's dictum,[3] that "as a very general fact the louder the endocardial murmur the less is the amount of valvular impediment." There is in truth no rule in either direction, but each case stands by itself.

A true estimate of the gravity of a lesion can only be gained by a general survey of the case in the broadest possible light; to determine, first, what has been its effect upon the heart itself, and then how far its influence has extended beyond this organ. If it is found that a murmur is present—no matter at which orifice—and that there is no change in that part of the heart upon which the strain first comes, and if it is also known that this murmur has existed long enough for the effects of increased work to be manifested, then it follows that the lesion is trivial and stationary and may remain so for an indefinite time. On the other hand, if hypertrophy or dilatation, or both, exist, their degree is a test of the actual interference with the heart in its work. Due weight is also given to the character of the pulse and to symptoms such as

Digitized by Google

dyspnœa or palpitation or syncope, and to any evidence of interference with the pulmonary or the systemic circulation or of the presence of associated disease. It is, however, necessary not only thus to check the special physical signs of valvular disease, but also sometimes to estimate the value of symptoms by physical signs. When this happens it is usually in young patients who are far removed from the class to which I shall next refer. A short time since I had under observation a young man who suffered from most alarming cardiac symptoms, of which a very grave view had been taken, frequent attacks of palpitation and dyspnœa with tendency to syncope being associated with a mitral systolic murmur and a moderate amount of dilated hypertrophy. Betweenwhiles, however, the heart was capable of steady and efficient contraction. It appeared to me that the phenomena were serious, out of proportion to the actual degree to which the organ was affected, and that the outlook was therefore favourable as to both the danger of the paroxysms and the prospect of ultimate improvement, and I am informed that time has shown the truth of this conclusion.

I have referred to conditions in which the physical signs may attract more attention than is their due. There is an opposite group, especially associated with advancing years, where they are apt to be by no means proportionate to the gravity of the actual state. In this case an intelligent consideration of the symptoms is essential, since they are of greater importance than the physical signs. For instance, a man beyond middle life, whose general nutrition is failing, suffers from shortness of breath and a tendency to palpitation. The heart's action is found to be somewhat feeble, and that is all. And yet fatty degeneration exists, from which the patient may at any moment die.

The importance of history, the second factor in prognosis, is never underrated by the practical physician. By it are determined the origin of any morbid state, the length of time that it has existed, and its tendency to development in one direction or in another, and an accurate appreciation of the information which it conveys is of the greatest value. Where valvular defect is due to acute endocarditis it is important to know whether there is a liability to a fresh onset of the malady in which it originated. For instance, when endocarditis arises during the course of an acute specific disease such as scarlet fever, which usually makes one attack only, the prospect is better than in the case of acute rheumatism, where recurrence is common, and often lights up fresh endocardial inflammation. Or the history shows that a murmur may be due, not to endocarditis, but to weakness of heart following acute illness or originating in anæmia, in which event there is a reasonable prospect of cure. Or the course is perhaps preventable or more or less removable, as when avoidable muscular strain produces cardiac dilatation. Or it is a diathetic condition, such as gout, which can be kept in check, but not eradicated. Or the affection may originate in a persistent and irremediable condition, as when dilated hypertrophy results from chronic Bright's disease or from the arterial degeneration of age. In every case a recognition of the cause of a cardiac lesion, and therefore of the degree to which it may be influenced or removed, enters into a rational prognosis.

It is difficult to over-estimate the value of a knowledge of the length of time that a heart lesion has existed. I will illustrate this point in the case of acute endocarditis. It has been pointed out that it is impossible to determine during an attack of this inflammation what will be its ultimate outcome. Walsh[4] says: "Viewing all forms of valvular impediment as a single group, it is not possible to make any statement of the least utility on the question of duration. Nay, even if any individual disease of the whole number be selected the extremes of brief and of protracted course are found to lie so widely apart that it becomes practically useless to strike a mean. ..... We must be content to register the unexplained truth that all forms of valvular disease may, on the one hand, prove the main instruments in rapidly killing, or, on the other, remain for a well-nigh indefinite period subjectively latent." And with this Latham's testimony accords[5]: "Such cases as have fallen in my way have taught me that the period to which life may be continued is very various. It may be a few months only, or a few years, or it may be for many years, even ten or twenty or thirty. Of these facts I am certain, but I cannot array them numerically and statistically; and because I cannot I can determine no relative proportion between those who survive months and those who survive years, or those who survive few years and those who survive many, yet the facts are sure." Walsh is unable to account for so wide a divergence, but Latham's explanation is as follows[6]: "When the heart is left in a state of unsoundness from past inflammation two principal consequences are to be expected—either there may be a renewal of inflammation in the unrepaired structure, or this remaining as it was left may become the element of further material changes in the whole organ. ..... The latter consist in alterations of bulk and size and shape and capacity, no other causes being engaged in bringing them about than those which are constantly at work in the healthy heart—namely, its own vital movements; only they are now at work with more or less energy than is either natural or healthy or they are at work without their natural and healthy harmony."

Considered from the point of view of pathological anatomy the result in acute endocarditis may be as follows. First, resolution, with removal of the products of inflammation and consequent disappearance of all abnormal physical signs. I believe this to be one mode of termination although this view is not universally held. Walsh[7] says: "An indubitable endocardial murmur, holding on from the beginning to the end of the acute disease, never, so far as I have known, totally disappears in after life." It will be allowed that murmurs are sometimes met with having all the characters of those due to endocarditis, and that they may disappear with convalescence from the fever or comparatively soon afterwards. I have myself met with what I have believed to be instances of this complete recovery. It has been urged that because the murmur does not persist therefore it cannot be due to inflammation. This important point is well argued by Byrom Bramwell,[8] who arrives at the conclusion in which I have expressed my own belief. Latham,[9] indeed, asserts that out of a series of 63 cases of rheumatic endocarditis "perfect reparation occurred in 17; for in these the murmur ceased entirely." And Gibson[10] records the recoveries from mitral endocarditis as 25 out of 51. This is so large a proportion that the doubt arises whether in some the murmur was not due to a cause other than inflammation of the endocardium. Resolution then being recognised as one mode of termination of acute endocarditis, undoubtedly a more usual result is the subsidence of inflammation but the persistence of its products. The young connective tissue growth in the affected portion of the endocardium goes through the same changes which occur in similar tissue elsewhere; it matures into fibrous tissue, which as it develops tends to contract, and therefore the valve-segments become more or less thickened, and perhaps distorted to such a degree that their function is permanently interfered with.

Pathologically, therefore, the result in all hearts thus affected is the same—the persistence of the matured products of inflammation. But the practical difference between one heart and another is great. In the one, perhaps, "a little ridge on the surface of a valve, a little granulation on its free edge, a little thickening or shortening of a tendinous cord"—possibly so slight a change that, though permanently marked by inflamation, the valve is practically perfect and no murmur exists, anyhow too trivial to give rise to definite interference with the function of the organ. In the other the self-same morbid process results in some valvular deformity, forming an obstacle before which the heart speedily fails. Pathologically identical, the outcome of the same affection, clinically the position of these two hearts is widely different. "The renewal of inflammation in the unrepaired structure" may occur in one of two ways—either by repeated attacks of acute inflammation similar to the first or by the passage of endocarditis from the acute form into the chronic. Latham[11] says: "When acute rheumatism has been once suffered in early life there is a fearful likelihood that it will be oftentimes suffered again. Moreover, the first attack is generally the type of every attack which is to follow; they will all take the same course and involve the same structures. If the first involve the heart, so probably will they all."

No one will dispute the liability of acute rheumatism to recur. Yet in my own limited experience it is not very exceptional for this fever to attack a patient in early life and not again, although many years may have elapsed. For instance, the other day I saw a man, aged twenty-seven years, who had suffered from rheumatic fever once only at the age of three years; a loud aortic systolic murmur existed, but without symptoms. And exception may also be taken to Latham's second point—that the first attack involving the heart all the later will probably do so too. For I do not think that it is rare for acute rheumatism to recur without the renewal of endocarditis. This is a point upon which it is not easy to speak dogmatically owing to the difficulty in determining that the heart does remain free from fresh inflammation. But it is fair to infer that this is so when the disturbance of the organ is not out of proportion to the general symptoms of fever, and no changes can be recognised in the cardiac area either during the acute stage or afterwards.

Opinions differ as to the frequency with which acute endocarditis passes into chronic inflammation. Latham [12] says on this point: "This I believe to be a fact which, if not true in every instance, is true in the majority—namely, that after inflammation of the endocardium has ceased, whatever remnant of unsoundness is left it continues ever after without increase in its own kind. After the lapse of years the very appearance of all we find seems to testify that it has long been stationary ..... and when the results of clinical observation are compared with those of morbid anatomy they will be found to testify the same thing." This important question is not adequately discussed by pathologists. You, Sir, point out the reason for this when you say:[13] "Specimens of endocarditis in this early stage are frequent enough. But it is not easy to say what occurs next in the process because we do not have many opportunities of seeing the intermediate conditions between this which is found in cases of death from the acute disease which causes the endocarditis and that advanced state of change in the valves which long afterwards proves fatal by disabling them. It appears to us that in the interval between acute endocarditis of rheumatic fever and the death long after from valvular disease of the heart many frequent repetitions of the inflammation must occur. Sometimes we find inflammatory products of two distinct dates on the valves, some recent, some older. But more usually a chronic state of inflammatory irritation persists, slowly changing the valve." Judging by clinical evidence my own experience points to the view that both these things happen. While in many instances there is only too good reason to conclude that the mischief is progressive, yet in some acute endocarditis comes to a definite end and no further change takes place in the tissue which has been the seat of inflammation. I have met with many cases in which no perceptible alteration either in the character of the murmur or in the general state of the heart could be detected at successive examinations, in some instances extending over a considerable number of years. It is reasonable to conclude that if the condition of the organ is thus stationary from the clinical point of view it only remains structurally unaltered. On the other hand, instances are only too common in which it is plain that the valvular lesion is progressive, and where the obvious inference is that chronic endocarditis has carried on the work begun by the acute inflammation.

It has thus been seen that the results of acute endocarditis, both pathologically and clinically, may vary within the widest extremes, and that no data exist by which it can be foretold during an acute attack what will be the ultimate position of any given case. How, then, will this most important question be answered? The problem will be solved by time alone. Let me remind you of the statement which I have already made, that a knowledge of the length of time that a heart lesion has existed is of the greatest value in prognosis. Endocarditis must be estimated by the results which it produces—the damage which has been done to the heart in a given time is a test of what will happen in the future; and prognosis becomes a problem in proportion. What, then, are the indications that a condition is on the one hand grave in its tendencies and on the other unimportant? The only test is the degree to which the heart has become secondarily affected, the evidence showing that it is hampered in its work. The presence of hypertrophy, the existence of dilatation, and their amount, signs of defect in the conduct of the circulation in the lungs or in the systemic circuit,—these it has before been said are what have to be sought. Let it now be supposed that the patient comes under observation some considerable time after an attack of acute endocarditis—it may be twelve months or two years or longer—and that a murmur is present. Prognosis becomes, as has been said, a problem in proportion. If the heart is in a certain state at the end of a certain time, what will be its condition in six months or twelve months or in five or ten or twenty years? And the longer the interval that has elapsed since the acute inflammation the more certainly can this question be answered. If in the same period one patient has arrived at the stage of dropsical effusion, while another has a much enlarged heart which can still, however, overcome the obstacle to its work; and another is unconscious of disease, and there is but slight increase in cardiac size and strength; and in yet another, no change whatever has occurred, the inference is plain that as it has been in the past, so will it probably be in the future—disease that has advanced will continue to increase—that which has been quiescent will remain so still. And through the whole series the foundation of prognosis is time—time and the changes which it has wrought.

I will conclude the consideration of the position of history by reference to a case which well illustrates its importance. Nearly eight years ago I saw in consultation a patient who had been informed that he was suffering from aortic aneurysm. The existence of disease had been discovered by accident and had not before been suspected, the patient feeling in his usual health. I found a most intelligent man, fully able to grasp the bearings of all that was said respecting his condition. The heart was enormously enlarged and hypertrophied; the impulse was so forcible as to shake the chest-wall and could be plainly felt through the clothes. Although I was of opinion that the physical signs, into which I need not enter, did not justify the diagnosis of aneurysm, yet they were not such as altogether to negative its existence. But I was much struck with the point already mentioned—that the trouble had been discovered by accident and not from symptoms complained of by the patient, who was exceptionally intelligent and observant and had led an active life. It appeared to me that a lesion accompanied by cardiac action differing so markedly from the normal, if of recent origin, could not arise without attracting the attention of the patient; and on careful inquiry it came out that the strong beating of his heart had been noted in his early adult life; and, further, that when he was a little child his father once came into the nursery when the boy was undressed and observed something which led him to bring the family medical adviser, who examined the chest. I therefore concluded that the patient had grown up with the lesion that existed, so that to him it gave no abnormal sign. It followed that aneurysm, which would be a recent development, did not exist. The prognosis attaching to the latter being thus set aside the question arose as to what the future had in store. On the principle which has been already discussed it was argued that if compensation was so complete that the heart, although thus enormously enlarged, had been able through all these years to do its work in such a way that an active man had no suspicion that it was otherwise than normal, there was no reason why it should not long remain equally efficient. As a matter of interest, and as showing how inconclusive were the physical signs, I may add that as opinions so divergent were given upon a subject of such importance the patient was examined in London by two eminent authorities, one of whom came to the conclusion that aneurysm existed, while the other agreed with my view of the case. The patient, after hearing either diagnosis fully argued by its supporter, made up his mind that the balance of evidence was against the existence of aneurysm, and laid his plan of life accordingly. This was nearly eight years ago. I have examined him at intervals since and have been unable to detect any signs of advancing disease; he is not conscious of any trouble; he leads a busy and fairly active life and looks the picture of health. I have gone thus fully into this case because it is a forcible illustration of the value of a knowledge of the past as a guide to the present and the future. A most important decision turned upon the history, and the result has proved that reliance was rightly placed upon its indications.

An acquaintance with the course which is usually run by a given form of heart disease is one of the factors which have

[12] Loc. cit., p. 274.
[13] Wilks and Moxon: Pathological Anatomy, third edition, p. 134.

Digitized by Google

been enumerated as entering into prognosis. From what has already been said it will be plain that this knowledge often cannot be applied with sufficient accuracy to be of much value. It has been seen that in acute endocarditis it is practically useless for determining what will arise in a particular instance. Nor, viewing all forms of chronic valvular impediment, in whatever way originated, is it possible to make a statement with regard to any one of them that will necessarily hold good of a given case. A lesion that in one instance may end fatally within a few months may in another be consistent with long life and practically good health. It is, however, recognised that each form of valvular disease has certain general tendencies and that some of these are more serious than others. The relative gravity of valvular derangements is variously estimated by different authorities. Walsh[14] places them in the following descending series: tricuspid regurgitation, mitral regurgitation, aortic regurgitation, pulmonary constriction, and aortic constriction, tricuspid constriction and pulmonary regurgitation being too little known to be placed in position in the list. The worst results follow those lesions which directly obstruct the circulation behind them. Hence tricuspid regurgitation has the first place, hindering as it does the return of blood from the whole of the organs and tissues of the general circulation, the heart itself included. Similarly mitral disease, the two forms of which come next in the series, causes obstruction to the passage of blood from the lungs, and consequently tends to produce the whole series of pulmonary complications which are due to this back-pressure. On the other hand, lesions of the arterial orifices—the aortic and the pulmonary—so long as they exist alone, do not affect the circulations behind them, protected as they are by the auriculo-ventricular valves; and the result turns therefore solely on what effect is produced upon the ventricle itself and how far there is interference with the supply of blood to the artery. Apart from the liability to sudden death aortic regurgitation is much more serious than obstruction at the same orifice because of the tendency to over-distension of the ventricle during diastole. Of all valvular lesions aortic obstruction is the most favourable, the left ventricle frequently undergoing hypertrophy sufficient to overcome the obstacle at the orifice of the aorta. Pulmonary constriction has probably no more serious tendencies than aortic obstruction. It is well known that the sufferer from certain forms of valvular disease is placed in a better position, especially as regards the prolongation of life, by having one or more other forms of affection of the orifices added to that which already exists. For instance, there is less liability to sudden death in aortic regurgitation if it is associated with mitral incompetence. Probably the regurgitation through the mitral orifice during the systole of the ventricle lessens the amount of blood driven into the aorta, and therefore the quantity and force of that which distends the ventricle during the succeeding diastole. Another familiar illustration is afforded by the effect of tricuspid regurgitation in relieving the pressure on the pulmonary circulation caused by mitral disease. It has doubtless fallen to the lot of most to meet with cases in which urgent lung symptoms have been caused by the position of the pulmonary circulation between the obstruction to the onward flow due to affection of the mitral orifice on the one side and the increased *vis a tergo* of the hypertrophied right ventricle on the other. When at last the tricuspid valve gives way part of the force of the hypertrophied ventricle is now expended in returning blood into the auricle, and thus the tension in the pulmonary circuit is lessened and the urgent lung symptoms are relieved, though at great cost as regards the systemic circulation.

I have before pointed out that the prognosis of chronic valvular disease resulting from a non-recurrent specific fever is more favourable than that originating in acute rheumatism, inasmuch as further attacks of the latter may occur, bringing with them fresh risk to the heart But the prospect is better when the valvular change is due to the endocarditis of rheumatic fever than if it results from inflammation that is chronic from the first. For while the former may remain quiescent unless the valve is attacked afresh during a recurrence of the fever the latter is commonly due to some persistent cause leading to progressive inflammation with its increasing valvular deformity. An exemption may be made in the case of endocardial mischief arising in old people. In my experience it is here of little practical moment, slow in progress, and causing but slight disturbance in the function of the affected valve and altogether of secondary importance to the degenerative changes in the vascular system generally, of which it is a part.

Time fails me to dwell upon the cause of chronic degenerative changes occurring in the heart wall. When fatty degeneration—the most important of these—is once established it tends to increase owing to the persistence of its cause. Similarly no prolonged consideration can be devoted to the prognosis of hypertrophy and dilatation. Their fate is bound up with that of their cause As this is usually persistent and often progressive the secondary cardiac enlargement is correspondingly permanent and tends to increase. The greater the hypertrophy in proportion to dilatation the better will the extra work be done and the difficulty be overcome. But only while the nutrition of the heart remains good. If the time comes that degeneration begins in the hypertrophied wall, the balance between work and power is disturbed never to be restored. This is so commonly illustrated in the late history of chronic Bright's disease. When renal inflammation becomes established in a patient whose nutrition is good the increased vascular tension is met by hypertrophy of the left ventricle, and the balance is thus so well maintained that the heart carries on with ease the greater work. But let the patient pass on to the time when the nutrition of the hypertrophied wall tends to fail; the strength of the heart is diminished while the calls upon it remain, and the symptoms of cardiac distress arise.

The liability to sudden death is an important aspect of prognosis. In the minds of the laity heart disease of every kind carries with it this awe-inspiring risk; and to inform a patient that his heart is not sound is to condemn him to a life of miserable uncertainty. The physician, however, knows that this danger attaches chiefly to certain forms of cardiac affection; it is therefore his duty to relieve the patient of the dread of this accident in any case when it is not likely to happen. Sudden death may occur in certain forms of chronic valvular disease, in dilatation, where degenerative changes exist, and from rupture of the heart or an aneurysm of this organ. It is well known that the lesion which carries with it by far the greatest risk of sudden death is aortic regurgitation. It is said by some authorities that this accident is liable to happen even when there is comparatively little regurgitation. Walsh[15] quotes a case in which there were absolutely no symptoms of disease, and there was neither hypertrophy nor dilatation of the ventricle, and yet the patient dropped down dead. He mentions, however, that the superficial pulses were markedly visible. In my own limited experience I have not seen the tendency to fatal syncope unless the regurgitation is considerable and the ventricle is correspondingly enlarged. It will be noted that in Walsh's case, while the ventricle is said to have been normal in size and force, the superficial pulses were markedly visible. I have never met with the characteristic pulse of aortic regurgitation when dilatation of the ventricle was not present, and on theoretical grounds it is not plain how a pulse indicating considerable regurgitation can exist while dilatation is absent, since the ventricle has to contain an increased amount of blood. Short of the existence of distinct secondary dilatation I should regard a patient with aortic regurgitation as safe from fatal syncope. On the other hand, it must be borne in mind that many in whom aortic regurgitation and its accompanying changes are extreme die, not suddenly, but by gradual increase of trouble. And, further, that there is less tendency to this mode of death when mitral regurgitation is added to aortic. One other valvular lesion sometimes ends abruptly, that is, mitral regurgitation. This does not often happen and is not to be feared unless compensation has failed. But that it may occur is impressed on my mind by the memory of an occasion when I discussed with a medical brother and the friends of the patient the course of life that should be followed, and death from syncope ensued within a short time of our leaving the house. The remaining varieties of valvular disease may be regarded as practically free from this risk. The same cannot, however, be said of dilatation, where the weak thinned wall sometimes unexpectedly ceases work.

It is, however, the degenerations which supply the majority of the instances of sudden death. Angina pectoris is notably a malady which tends to terminate in the way under consideration; and in fatal cases some change in

[14] Loc. cit., 392.

nutrition is practically always found — usually fatty degeneration of the muscular substance, and especially affection of the coronary arteries interfering with the nutrition of the heart wall. Fatty infiltration, if excessive, may end in sudden syncope; this is much more likely to happen in the weak heart of true fatty metamorphosis. But of all conditions the danger is most imminent when a degenerate heart has to face increased arterial tension. Here the type of cardiac action indicates the peril that threatens. The pulse is quickened; it may be irregular and intermittent or fairly regular, and is often of good value, but its notable feature is high tension. The short and toneless first sound of the heart is hurriedly followed by a ringing aortic sound. This kind of action marks a ventricle that can barely hold its own until the strain is taken off by the closure of the aortic valves, and it is plain that the patient lives on the brink of a precipice over which a trifling extra demand upon the heart may at any time determine his fall.

The last division of prognosis, which takes into consideration the special features of a given case, includes many factors, such as social status, sex, temperament, and general habits, and the condition of other organs; but their influence cannot be discussed in detail. Excepting the state of other viscera, perhaps the most important of these is position in life. If the sufferer from cardiac trouble can be placed in an environment as nearly ideal as is attainable by the lavish expenditure of care and money his prospects differ much from those of another who has to work for his bread in the station in life which he may chance to occupy when the malady overtakes him. This is exemplified in the case of acute endocarditis. I hold strongly that it is of the greatest importance to keep the heart as far as possible at rest for some considerable time after an attack of acute endocardial inflammation. Rest is the first essential to the cure of inflammation and the removal of its products. This is so obvious in the case, for instance, of a joint that it is always recognised, and the surgeon never grudges the time, however long, spent in the endeavour to secure a healthy limb. And it behoves the physician to keep just as clearly in view the state of the recently inflamed valve. When the social position of a child suffering from recent endocarditis will allow it is my practice to enjoin the retention of the recumbent position for from three to six months. After this, if the murmur persists, the gentlest exercise is gradually allowed; but for several years all violent exertion is forbidden. At the same time great attention is paid to the general health. The intelligent coöperation of the friends, and as far as possible of the little patient, is needed to the success of this method. But where it has been practicable I have seen reason to be well satisfied with the result. In the case of older patients the treatment is approximated to the above as closely as circumstances will allow. The prognosis of acute endocarditis much depends upon this one question, whether or no the heart can for some time be saved all but the "irreducible minimum" of work. Any trouble and pains are well expended that will lessen the prospect of valvular disease in after life.

Contrast with this the case of the hospital patient. The child or the young adult is treated for acute rheumatism accompanied by endocarditis, and the fever is quickly subdued. But the affected valve has not recovered its normal condition, even if active inflammation has subsided; it still remains a thickened and softened structure, ill fitted to withstand the pressure of the blood-stream. The whole future life may turn upon what the next few months will bring to this valve. And yet the exigencies of hospital work are such that the patient must be discharged when convalescent from the fever to take his chance with a still damaged valve. He receives excellent advice when he leaves; the boy must not do as boys are wont to do; the older patient is warned against those things which are placed in his way by his lot in life; the wise counsel is not followed, and the still softened valve gives way before the blood-current, or acute endocarditis becomes chronic inflammation, with its progressive increase of mischief. In heart disease there is more truth than is commonly the case in the saying that there is one law for the rich and another for the poor.

In conclusion, I am constrained to put forward a plea for mercy in the prognosis of heart disease. No one is exempt from the human attribute of liability to err. In the case of the physician this imperfection may be viewed in two aspects—as it affects his own reputation and in its influence upon the subject of his error. It is with the latter that I am now concerned. The philosopher Bacon might well have had in view the prognosis of heart disease when he counselled "not to engage a man's self peremptorily in anything, though it seem not liable to accident, but ever to have a window to fly out at or a way to retire." All must be familiar with instances of the occurrence of the unexpected. I remember a man, fifty-nine years of age, who was the subject of most pronounced valvular disease. When twenty years old he was warned that his life was in danger and at the age of forty years was condemned to die within the year. The other day I saw a young man who had a mere suspicion of aortic obstruction; ten years before it was said that he might die at any moment. Some twelve years ago I examined a child with marked mitral stenosis and dilated hypertrophy—such a condition as might well have led to an early catastrophe; she has grown into a well-developed young woman, who would not be suspected of the lesion she carries. A lady, aged eighty-four years, has suffered for nearly twenty years—sometimes in a most alarming form—from all the symptoms of cardiac weakness commonly associated with fatty degeneration, and she still lives.

The wider experience becomes the more does certainty give place to probability, and it is wise to give due weight even to possibilities. And especially should this be the case in dealing with disease of the heart, which carries with it to the sufferer the thought of constantly impending evil. It has been my lot from time to time to meet with those who have been told, as has been proved without sufficient reason, that some grave cardiac lesion existed. To restore hope to life, to give the patient to the full the benefit of such doubt as may attach to the nature of his condition and the uncertainty that too often attends the prediction of his future, surely this is not only justifiable but also right, and the lightening of the depressing influence of fear and dread will in itself tend to avert the danger that may threaten.

For the imperfect and inconsequent manner in which this lecture has been placed before you I crave your indulgence. I have touched only the borders of a subject whose importance deserves far abler treatment than it is mine to bestow.

Inaugural Address

ON

SOIL AND CIRCUMSTANCE IN THEIR CONTROL OF PATHOGENIC ORGANISMS.

Delivered before the Midland Medical Society on Oct. 21st, 1897,

BY SIR RICHARD T. THORNE, K.C.B., M.B. LOND., F.R.S.,

PRINCIPAL MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD.

MR. PRESIDENT AND GENTLEMEN,—It has long been matter of observation amongst those who are accustomed to the investigation of causes of disease that certain infectious diseases tend to recur periodically, after intervals more or less long, in the same localities—whether these be houses, villages, or towns — under circumstances that can hardly be explained except on the assumption that the specific infections with which these diseases are associated have in such localities contrived to retain their vitality during the intervals and to maintain themselves outside the human body. These occurrences stand in striking contrast with other prevalences of the same diseases, often of equal virulence and extent, but which exhibit no tendency to recur; and the question naturally arises how such difference in the behaviour of disease can be explained.

Similarly, there are individuals who, on a single exposure to an infection, do not fail at once to contract the disease in question; whilst in contrast with these persons we know of individuals who are subjected to maintained risk and exposure of precisely the same sort, and who seem from the very first to possess a natural immunity against some

Digitized by Google

particular infection. To explain this by saying that in the one case there was a predisposition to the disease and that in the other case the predisposition was lacking is but to re-state the fact and to leave the problem unsolved. Hence here again some explanation of the observed difference has to be sought. Since we have come to learn that the specific infectious diseases are caused by the reception into the system of definite micro-organisms, each of which has its own life-history and physiological properties, and a number of which give evidence that their power of reproduction, their capacity for retaining certain definite characteristics, and even their ability to maintain their existence are dependent on their surroundings, it has become important to ascertain how far this question of surrounding serves to explain differences of behaviour in disease such as those to which I have referred.

The specific organisms of disease must be looked upon as subject to much the same laws as those to which the lower forms of plant life are subject. If they are under the influence of surroundings which supply all their wants they may be expected to flourish and to multiply; if some condition important to their well-being is lacking they may be expected to suffer diminution or even loss of some notable property, and to be modified accordingly; and if their surroundings are inimical in a higher sense of the term they may be unable even to maintain their vitality. The question of environment thus comes to be one of primary importance, and in referring to the influence of soil and circumstance in their control of pathogenic organisms I desire to include consideration of all the surroundings to which such organisms may come to be exposed, and to consider how diversity of soil and circumstance may tend to explain the different behaviour of infectious diseases as regards localities and individuals.

Permit me to be more precise in defining the position which I advance. In the decennium 1871–80 the county of Durham as a whole had a far higher rate of mortality from "fever"—mainly enteric fever—than that prevailing in any other part of England and Wales, and although a large and substantial diminution in this rate took place in that county, as it also did in England and Wales as a whole during the decennium 1881–90, yet Durham continued to maintain her pre-eminence in regard to death from "fever." This position of unenviable notoriety still belongs to the county of Durham; indeed, since the expiration of the last decennium the Registrar-General has drawn especial attention to the habitually recurring and undue prevalence of enteric fever in a tract of country including much of Durham and extending along the east side of northern England. There are counties in proximity to Durham in which during the same twenty years the "fever" death-rate has barely reached half that with which the Registration County of Durham has become identified. What are the characters of the soil—non-living or living—into which the pathogenic organism of enteric fever falls in many districts of Durham, which are lacking when the same disease occurs in neighbouring districts; what, in short, are the circumstances and surroundings which favour its life-processes so much in the one instance and which are only about half as potent in districts near at hand?

So, also, there are towns in different parts of England from which enteric fever is rarely absent and in which it periodically recurs as a somewhat wide prevalence or even in epidemic form; whilst, on the other hand, there are towns and communities of equal size near by, where the conditions by which imported infection is surrounded, and where the soil into which the pathogenic organism is received are inimical to its life-processes and where it soon dies out. It is not that the organism itself differs at the outset. Cases are known in which infection from a town which suffers habitually from enteric fever, but which—by reason perhaps of a wholesome water service—rarely suffers in epidemic form, is imported into another where the disease is rarely known; but gaining access to a public water service the result is a severe but an altogether transient epidemic. And, once more, I have known a house standing in large grounds to be smitten with enteric fever on three different occasions, the disease affecting in succession three different sets of tenants; and although between the second and the third occurrence the dwelling had been untenanted for nearly two years, yet the disease reappeared amongst the new tenants within a few weeks only of their occupation of the dwelling.

Soil, in its ordinary geological sense, has often been credited with having concern with persistence and recurrence of enteric fever, and since the discovery of the Eberth bacillus additional importance has come to be attached to this view. That bacillus, like other pathogenic organisms, is distinctly affected by its surroundings. Light does not favour its life-processes; direct sunlight is distinctly inimical to it; very high or low temperature affects its power of self-multiplication, especially when dryness is combined with the extremes of temperature; and there are some grounds for believing that it is not ordinarily capable of resisting for any long period of time submergence in water. Judging by analogy it must also be assumed that it requires its proper nutriment in order to thrive and to multiply.

Under these circumstances we can easily realise that the question of the maintenance or the destruction of this pathogenic organism outside the human body may largely come to depend upon the condition of the soil on which the excretory matters containing it may find themselves. On the one hand, a hard and somewhat impenetrable surface exposed to the sun and to a dry air as well as a soil which contains but little organic matter have often been assumed to be unfavourable to the extension of enteric fever; whereas, on the other hand, a loose and loamy soil, which is organically polluted and which at the same time permits the penetration of the organism and provides it with means of nourishment and a sufficiency of moisture, has been credited with the power of maintaining the vitality of the organism, of securing its multiplication, and of storing it up without its undergoing any material modification in its physiological properties, pending its entrance into the human subject as the result of its being washed into a well or being forced out of the soil into the surrounding air.

All this, however, had been matter of surmise, and it is only recently that any systematic attempt has been made to study how far conditions of soil are concerned in enhancing or in controlling the operations and properties of the enteric fever bacillus. Under these circumstances I last year procured the sanction of the President of the Local Government Board to commence sustained investigation of this subject. I was largely influenced in seeking this sanction by the consideration that in the Medical Department of the Local Government Board we had already procured valuable evidence in proof of the fact that the organism which in its life-processes in peaty soil is the ultimate cause of lead-poisoning which follows the consumption of certain moorland waters is in a high degree dependent for its vitality and its power for harmfulness upon the condition of the soil whence the waters in question are derived. Already some significant results have been obtained as the outcome of certain investigations which Dr. Sidney Martin has been carrying out for the Medical Department of the Local Government Board. These results will appear in detail in my official report for 1896–97, shortly to be issued, but in the meantime I may give a brief summary of that which has already been ascertained. Dr. Sidney Martin made one set of experiments with soils containing a large quantity of organic matter, some of these being derived from localities where enteric fever was wont to recrudesce from time to time. Having placed samples of these soils in flasks, and having completely sterilised them, he inoculated them with one and another culture of the typhoid bacillus, and examination of soils thus treated at intervals varying from about a fortnight to fifteen weeks showed that the bacilli had invariably retained their vitality, that in some cases the whole, and in others a part only, of the experimental soil had become pervaded by diffused growth of the bacilli; and that the extension of the growth bore relation to the temperature at which soil of this class was incubated, and also to the amount of moisture in the experimental soil. The important conclusion is, however, reached that under the conditions of a laboratory experiment soil such as that described affords, after complete sterilisation and at ordinary temperatures of the atmosphere, not only a medium in which the typhoid bacillus can retain its vitality, but one in which it is capable of multiplication and of spreading abroad. In the official report referred to, Dr. Sidney Martin only records the results of his experiments up to the end of March last, when his experience in this matter was limited to 105 days, or fifteen weeks; but his further investigations into this subject have already shown that in a soil such as that referred to the retention of vitality and the power of spreading abroad of the typhoid bacillus have been maintained at varying temperatures for periods of no less than 214 and 268 days—that is to say, some seven and nine months.

Dr. Martin next proceeded to make similar experiments

Digitized by Google

with two soils of quite different sorts. One was a firm, crumbling, peaty soil, and the other a red sandy soil from beneath the peat, both being collected at a distance from human habitations. These so-called "virgin" soils were first sterilised and then they were inoculated with culture of the typhoid bacillus in precisely the same way as had been practised with the organically polluted soils. Some samples were then inoculated at the temperature which had been found in earlier experiments to be most favourable to the growth of the bacillus in soil, other samples being kept at the ordinary temperature of the laboratory. The result was in striking contrast with that of the experiments carried out with the organically contaminated soil. In all the previous testings the typhoid bacillus had retained its vitality from the first, and in most of them there had been spread of the micro-organism from the centre of the soil, where the original inoculation had been made, to the periphery. But with both sets of these virgin soils no sign whatever of vitality could be discovered as the result of testings fourteen, twenty, and twenty-three days after the inoculations.

Thus far these experiments have only been carried out under laboratory conditions; they have had concern only with the vitality of the organism in its vegetative aspects; they have been carried out with sterilised soils, that is to say, soils where the typhoid bacillus was free from the influence—whether favourable or inimical—of other micro-organisms in the soil; therefore they will have to be repeated on a wider scale and under circumstances more nearly resembling those met with in nature, and they must take cognisance, not only of the vegetative properties, but also of the physiological and pathogenic properties of the organism. But in the meantime they are of marked value in connexion with the question to which I am addressing myself and they may serve to teach some useful lessons. Speaking always with a due sense of the restrictions imposed by the artificial character and the limited number of the experiments thus far reported on, I may fairly maintain that we have reason for inferring that whilst one soil and set of circumstances are highly favourable to the vitality and propagation of the typhoid bacillus, another soil and set of circumstances are rapidly destructive to it; and we seem to be upon the border of a territory where some vein of actual knowledge is likely to be discovered which will materially assist, not only in solving the problem of the different behaviour of enteric fever as regards its persistence and recurrence in one and another dwelling, town, or district, but of further emphasising the value of that practice which has now so long been adopted in this country for the prevention of typhoid fever.

In order to give a practical aspect to this question let me recall some of the circumstances of the soil and surroundings which we have learned by experiment to be favourable to the vitality and multiplication of the typhoid bacillus. They are that the soil should be pervious, that it should be permeated with a sufficiency of decaying—preferably animal—organic matters, that it should possess a certain amount of moisture, and that it should be subject to a certain temperature. And then let us consider what means can be adopted to deprive the soil of one or more of these conditions which appear to favour the retention of the vitality and power of multiplication of the typhoid bacillus, and to prevent that organism from gaining access to the soil in the neighbourhood of human dwellings. To this end I would in the first place advocate the paving of open spaces about dwellings where these open spaces are of small area and are liable to become contaminated with excreta. In this way fouling of, as well as penetration by a pathogenic micro-organism into, the underlying soil is practically prevented. Indeed, it is well known not only that the paving of yards about small cottage and tenement property in towns has in its results been shown to be a public health measure of first importance, but also that the value of such a measure has depended largely on the use of a form of pavement which really ensures impermeability. In the next place it will be clear that organic and decaying refuse should be so dealt with as to prevent its contaminating the soil in the neighbourhood either of dwellings or of sources of water-supply. I need hardly point out here in detail what are the points to aim at in securing this end; but I may perhaps usefully approach the matter from the other point of view, and say that the midden-privy which still prevails in so many of our large midland and northern towns presents every feature that should studiously be avoided. Generally sunk below the surface of the ground, often open to rainfall, always storing up decomposing excreta and refuse in close proximity to dwellings, it provides almost every condition favourable to the production of nuisance, to the saturation of soil with filth, and to the setting up and maintenance of those very conditions which seem to be essential to the vitality and multiplication of the typhoid bacillus. The fact that with our present knowledge such a structure as the common midden-privy should not only still exist in our midst, but be clung to with a perverted tenacity, is in my opinion the greatest blot which attaches to English sanitary administration at the close of the nineteenth century. Apart from its sanitary aspect it is a system as degrading and ignoble as it is foul, and I trust the day is not far distant when we shall look back to it as a barbarism of the past. Firstly, then, let our aim be to maintain such a condition of cleanliness about our houses that the soil shall approach as far as practicable to the condition of those virgin soils which are inimical to the growth of the pathogenic organism under consideration.

The next points are to deprive the soil in the immediate proximity of dwellings and of wells, so far as this may be practicable, of those conditions of moisture and temperature which we begin to perceive may tend most to the multiplication of the enteric fever organism. We have as yet but little precise information on these points; but if we may judge by the very partial and as yet incomplete experiments made by Dr. Sidney Martin in this matter we are led to the conclusion that a porous and organically contaminated soil to which moisture in the form of distilled water has been added to the extent of some 35 grammes per cent., and having a temperature of some 37° C. (103° F.), seemed best adapted to the growth and the spreading abroad of the typhoid bacillus. Any material modification in the amount of moisture, and, above all, any reduction of the temperature down to that which may ordinarily be expected in soil, tended at once to retard and to check the growth of this bacillus. In so far, then, as we may be able to control conditions of temperature and moisture in the soil in the immediate neighbourhood of groups of dwellings, to that extent we may be able to acquire some control over recurrences of enteric fever. Here again I would give prominence to the systematic paving of house yards with an impervious material. Where open spaces about dwellings are large, and where organic pollution of surface soil is practically absent, we may rely, as inhibitive of this bacillus, on the influence of sunlight and of alternating weather; but in our towns the conditions have become too artificial and the open area about dwellings has become too restricted for us to hope that under the unnatural conditions which have been inducedby urban aggregations of dwellings, we have any right to expect the full benefit of Nature's remedies.

My reference to the question of soil temperature leads me to make a few remarks on another disease which is periodically very prevalent in some of our large urban centres. I refer to epidemic summer diarrhœa, so fatal to infant life. There is strong presumption since the late Dr. Edward Ballard's researches that the question of "soil" is in this disease a most important factor, and that the essential cause of it is bound up with the life-processes of a micro-organism—not yet definitely differentiated—which exhibits its vital manifestations in the superficial layers of the earth. But here, again, the differing circumstances of the soil would seem to have a most important influence in determining whether the organism is to live and multiply or whether it is to be deprived of its power for mischief. When it gains access to a soil that is sufficiently loose to be permeable to air and water, and which contains a sufficiency of that organic matter which prevails so largely about the densely peopled areas of our large cities and towns, then the maintenance of its vegetative vitality is likely to be ensured; and when, in addition to this, it finds itself in the presence of a suitable temperature and moisture combined, then its power of rapid multiplication and its full pathogenic properties seem to be ensured. Dr. Ballard, as you are aware, has propounded the thesis that these requisites are pre-eminently present when the subsoil water stands sufficiently near the surface to maintain by capillary attraction a slight amount of dampness in the surface soil and when the temperature of the earth at a depth of four feet reaches 56° F. Then it is, in his view, that the organism can undergo most rapid multiplication; and becoming air-borne as the result of physical actions, such as the rise and fall of subsoil water it can gain access to

Digitized by Google

food supplies, and, above all, to the milk, which is so commonly stored for infants in miserable pantries opening out on to small confined areas and yard spaces, where emanations from filth accumulations blend with those forced out from the soil itself. In this way the organism finds, according to Dr. Ballard, an appropriate medium for undergoing those life-processes which end in the production of a virulent chemical poison. Milk thus infected may be deemed to constitute a common vehicle for conveying to the infant this poison, the results of which are so terribly fatal in some of our large towns.

As consistent with the view that the influence of soil is a prime factor in this disease I may say that there are instances of towns standing almost side by side which, in density of population, in trade and occupation, in climate and other like conditions, exhibit no appreciable difference, and yet whilst one town is notorious for its ever-recurring autumnal diarrhœa mortality, the other stands out with equal prominence by reason of its maintained comparative freedom from this fatal diarrhœa. The circumstances of soil in one place are to be thought of as responding to the requirements of the micro-organism; in the other as failing to respond to them.

Let us again seek some practical application of the results of this research. First and foremost stands the need of a soil that shall be maintained as free as practicable from organic contamination; and in the narrow and restricted open spaces about our city dwellings this means such disposal of excreta as shall be free from nuisance, such means of storage of all domestic refuse in receptacles of limited capacity as shall prevent contamination of soil and air and shall necessitate frequent, even daily, removal; and, once more, it means the provision of an impervious paving for yards and courts so as to protect the soil, not only from contamination, but also from exposure to that heat which, in combination with moisture, can serve as an incubating chamber for this virulent organism. There is a further practical application. It is this. Feed no infants artificially on milk that has not been quite recently boiled. I say "boiled," because in the houses of the poor sterilisation apart from boiling cannot be expected. But I would add there is no sterilising apparatus that can give results comparable with those provided by nature in the healthy female breast; and I would venture further to maintain that no milk from the mammary gland of its mother ever caused the death of an infant from this specific summer diarrhœa.

Thus far I have restricted my use of the word "soil" to its geological sense. But for the purposes of my subject it should be made to include all the circumstances and surroundings to which a pathogenic organism may be subjected and in which it may find, or fail to find, the necessary conditions for retaining its vitality and for reproducing its kind. It was in this more general sense of the term "soil" that I referred at the commencement of my address to the question of individual predisposition to disease. As regards a number of specific infectious diseases, such, for example, as tuberculosis and diphtheria, we know that many people at the same ages and under similar external conditions are either constantly or at frequently recurring intervals fully and, so far as we can judge, equally exposed to the pathogenic organisms with which these diseases are associated, and yet, whilst some succumb to them at once, others exhibit no susceptibility to them, this immunity extending at times over a long term of years or being even permanent. Such persons as the latter must obviously receive into them the specific organisms in like manner with their less fortunate fellows; indeed, the organisms in question may be actually found in them on precisely the same mucous and other surfaces as those wherein they begin their career of mischief in the so-called susceptible persons; but in the so-called non-susceptible persons the microbes lack some one or more conditions necessary to their disease-producing function. This difference between impotency and virulence in the organism is doubtless very largely a question of surrounding circumstances; indeed, it may be essentially one of the soil on to which it has fallen.

How many thousands of persons must have consumed tuberculous milk without ever having contracted tuberculosis, whilst how many must be the infants who doubtless acquire tuberculosis through the same medium during the very earliest days of their lives. Or, again, how common it is to find the bacillus diphtheriæ on the faucial mucous surfaces of nurses and other attendants in diphtheria wards, whilst these persons not only are, but remain, quite free from disease, whereas, on the other hand, how fatal to others is the reception of these bacilli under apparently similar circumstances. The question is, I believe, mainly a question of soil in the widest sense of that term. In the case of tuberculosis there are grounds for believing that when tubercle bacilli carried aerially impinge on the healthy mucous surfaces of the mouth and, above all, of the nares, they are not only largely arrested where they first impinge, but are also rendered impotent for harm by the physiological and chemical characters of the material with which they come into contact. Such as reach the stomach without such hindrance, whether swallowed with the saliva or received in food, have to contend with the gastric juice, which is probably sufficiently inimical to destroy or at least attenuate them if they are not excessive in number or of superabundant vitality. And, again, it is highly probable that these organisms rarely make their way into the human system through the digestive tract so long as that tract is covered with an unbroken, undamaged surface of normal mucous tissue. In short, the condition of health, in its widest sense, is inimical in its refractory and resistant sense, to pathogenic organisms, because the normal healthy tissues do not afford them the means of retaining their vitality and of facilitating the reproduction of their own kind. In this connexion it is also important to remember that in healthy tissues pathogenic organisms meet with vast numbers of cellular bodies which are normally present in them, that a struggle for existence then ensues, that the pathogenic bacilli are often devoured—by phagocytic action—by the normal phagocytes, leucocytes, &c., and that we largely owe our safety from disease to such antagonistic action of our tissues. Some organs of the body appear to have this work as their primary function. Thus the tonsils, standing as advance guards near the entrance of the respiratory and alimentary tract, must arrest many an organism that is carried to them aerially; and as regards such a disease as diphtheria I feel convinced that the difference between contracting the malady and not contracting it has largely to do with the condition of the surfaces of these organs. If the tonsils are uniformly healthy there is safety; if they are in an abnormal condition, as, for example, abraded, congested, or inflamed, there is risk. But the amount and the vigour of the infective bacilli received has probably also to be taken into account, for even granting the presence on a healthy surface and in a healthy gland of micro-organisms and cells that contend with and are antagonistic to pathogenic organisms, the first set may be overwhelmed by reason of both quantity and quality in the invading organism. It is circumstances such as these that must be regarded as having a very direct bearing in determining predisposition or susceptibility to infection on the one hand and so-called immunity, or absence of predisposition to infection, on the other hand; the two sets of individuals equally exposed to infection being apparently subject to the same risk. It is, in short, a mere matter of soil and circumstance.

My reference to diphtheria leads me to refer to two matters which have a direct bearing on the subject before us. I have been credited with the assertion that faulty sanitary circumstances have no place in the production of diphtheria. I am not aware when or where any such assertion was ever made by me. But I am free to admit that I do hold the opinion that diphtheria is not caused by sanitary circumstances, however faulty they may be, apart from the reception on to the fauces or other susceptible surface of the diphtheria bacillus; and I have a profound conviction that, subject to the limitations just indicated, the diphtheria bacillus does not retain its specific properties or undergo in its life-processes the changes necessary to the production of a specific toxin when it falls on a sound or healthy surface. On the other hand, I have expressed a very definite opinion to the effect that whatever produces an abnormal and unhealthy surface of the tonsils or other parts of the naso-pharyngeal tract tends directly to provide a soil which favours the retention, and perhaps the acquisition, by the diphtheria bacillus of those properties by which it produces disease and death in man. And I have, by way of illustration, specified two forms of throat ailment which, more than any others perhaps, favour an enhanced virulence and power of multiplication in the diphtheria organism—namely, that form of throat which so often follows inhalation of an organically contaminated air, vulgarly known as "drain-throat," and that condition of the fauces and nares which is so constantly found in scarlet fever convalescents and which is regarded as a part of that disease. Allow me to quote a few words from my

Digitized by Google

published Milroy Lectures[1] on this subject: "I am inclined very largely to limit the operation of faulty sanitary circumstances to the production of a morbid state of the fauces which induces a local condition favourable to the reception of the specific organism of diphtheria." And referring to a particular prevalence of diphtheria in a midland town I went on to say that given "that form of sore-throat often identified with drain effluvia ..... it needed but a resuscitation of the diphtheria infection in order to the specific inoculation of such throats. In short, I am inclined to regard the influence of a sewage polluted air as operating in much the same way as the scarlet fever poison, in so far as predisposition to diphtheria is concerned." The matter thus becomes one of soil, these two conditions of throat bringing about a localised set of circumstances which are favourable to the reception, to the vitality, and to the various life-processes of the bacillus diphtheriæ.

The other point to which I would advert is that apart from the immediate production of a disease as the result of the impact and lodgment of pathogenic organisms, the essential functional characteristics of those organisms are liable to be affected according to the circumstances in which they find themselves when they have fallen on one or other soil. A property—say the virulence—of the organism may entirely depend on the question of soil and circumstance; in the one case the specific virulence may be enhanced, in the other it may be attenuated or even destroyed. The result that is to ensue must depend on a multitude of circumstances. Concerning many of these we as yet understand but little; concerning many more we are in almost complete ignorance. But we already know that one set of—say pathogenic—organisms coming into conflict with another set of organisms find that their quality of virulence and power of multiplication are favoured and increased; whereas another set from the same source, but reaching another soil, may find themselves in conflict with other organisms that tend to their destruction, the two being mutually inhibitive. I have long maintained that the virulence and even the specific quality of an organism may be a matter of progressive development according to soil and surroundings, and some twenty years ago I compared the process of the evolution of the property of infectiveness to those processes by which definite properties in plant life, such as colour and perfume, can be produced and can be modified or allowed to lapse in the hands of skilled horticulturists or in nature according to the surroundings to which the living matter in question is exposed, "the affair being," as I then said, "essentially one of soil." At one time this view met with but little, if any, encouragement from certain teachers and students of bacteriology. They inclined to the view that the specific qualities of pathogenic organisms were stable and not subject to modification. But much in the epidemiological behaviour of different infections has tended to a quite different conclusion. In 1883 my colleague, Mr. W. H. Power, F.R.S., laid down certain propositions with regard to the cholera microbe—propositions which fell on many an unreceptive ear. He maintained that the cholera organism "has phases in its life-history during some of which it has not and in others it has the power of producing cholera"; and he further expressed the view that when once this exotic organism is no longer liable to the conditions—local or climatic, for example—which in its home were wont to favour the retention or enhancement of its "malignant phase," the general tendency of the organism was towards its non-malignant phase.

At the present moment we seem to be on the high road to an absolute confirmation of these views. Koch's cholera vibrio can be found in abundance in a state in which morphologically, and in most other respects, it is indistinguishable from that which is in direct causal relation to cholera, and yet the organism is impotent to produce that disease. Dr. Cautley, experimenting with the typhoid bacillus, finds that its power of survival in milk is dependent to some extent on the number of organisms normally to be found in milk. Thus in cold weather, when the micro-organisms commonly present in milk are least abundant, the typhoid bacillus survives longer than in warm weather. Here we have another indication of the manner in which a pathogenic organism is influenced according to the qualities of the soil and environment in which it finds itself, and incidentally we may have some explanation of the seasonal behaviour of enteric fever—a disease which is more prevalent in autumn and winter than in the summer.

I referred just now to the antagonism existing between tissue cells and pathogenic organisms. Study of this question has also included that of the influence which micro-organisms of different characters exert upon each other when they come into competition. To a large extent the investigations made have been concerned with pathogenic organisms, and some valuable results have been obtained. Thus Dr. Klein showed some six years ago that whilst with cultures of either the malignant œdema bacillus or of the bacillus of grouse disease fatal results were invariably obtained on the inoculation of mice with each separate infection, yet when cultures of these microbes were mingled together and the mixture was injected into mice, very few of them suffered any illness at all. Here we seem to have mutual inhibition between two sets of organisms, the contrary action of one and the other being brought about by the circumstances under which the one or the other set or both sets of organisms found themselves placed on injection into the body of the mice, the result being determined by the nature of the circumstances and surroundings to which the organisms were severally exposed. In other instances we know that a condition of antagonism is brought about when the inoculation of an animal with a specific and commonly fatal infection follows its inoculation by an antecedent infection. In this latter case it seems clear that the first inoculation has so modified the otherwise receptive soil into which the second infection is received as to modify or even destroy its virulence. On the other hand there are instances in which toxic bacteria or their products used in advance for inoculation purposes make the soil—in this case the body injected—more receptive than it otherwise would be of a second specific infection. The inability to produce disease which different specific micro-organisms often experience when they are received into the human body may well be believed to be in part due to the presence therein, and the antagonistic action, of other organisms which are associated with the condition we call health; whereas, on the other hand, organisms which are either associated with conditions of unhealthiness or are themselves the cause of a condition of ill-health may well be believed to have at times the power of enhancing and of adding to the virulence of specific organisms which come into competition with them. In this way immunity, special susceptibility, and predisposition come to be in each case essentially an affair of the soil and circumstances in which one and another specific organism finds itself placed. If we limit the term soil to its geological sense the same holds good. The natural soil teems with micro-organic life; one thimbleful of ordinary garden soil which has periodically received a manurial dressing will contain from one to three million micro-organisms, and a soil which has long been free from any artificial process of manuring still abounds in micro-organic life. These organisms in their life-processes tend to the modification and often to the destruction of extraneous organic matter. Experience shows how often micro-organisms endowed with mischievous qualities lose the power for harm on reaching certain soils. But the normal and harmless micro-organic constituents of the soil may be overcome by the abundance of extraneous organisms, such as those having pathogenic properties and which on occasion find their way into the soil, and then the latter may not only secure for themselves a medium for their reproduction and periodic activity, but their mischievous qualities may even be enhanced.

It may possibly be thought that in the remarks which I have addressed to you I have dealt too exclusively with considerations bearing upon the duties of those who concern themselves with matters affecting public rather than personal health. I trust this is not so. Whether we limit the use of the term "soil" to its geological sense, or whether we make it include every "circumstance" affecting man and his surroundings through which pathogenic organisms are wont to reach the human body, I know no influence that can better be exercised for good with respect to the protection of the individual and the home than the wise counsel of the habitual medical adviser. He above all others is free from the suspicion of advising merely on some general principles and for the benefit of the community at large rather than for that of the individual. The guidance of those whose counsel is sought and trusted at times of sickness is that which will best ensure for households and individuals that when the

Digitized by Google

struggle with specific infection comes it shall be successfully met; and this can only be when there shall be ready in advance that condition of healthiness in its widest application which would appear to be antagonistic to pathogenic organisms and inimical to those life-processes which conduce to the production of their toxic poisons.

Introductory Address

ON

THE NEURON AND ITS RELATION TO DISEASE.

Delivered at the National Hospital for the Paralysed and Epileptic on Oct. 5th, 1897,

BY SIR WILLIAM R. GOWERS, M.D., F.R.C.P. LOND, F.R.S.,

PHYSICIAN TO THE HOSPITAL; CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

GENTLEMEN,—It falls again to my lot to welcome you to the course of lectures by which we endeavour to increase the practical service of this hospital, by enlarging the knowledge and power of those who choose to avail themselves of the opportunity, and take the trouble of coming to receive its gift. We revert, moreover, to the former custom from which last year we departed, and interpose no pecuniary obstacle, except in the case of those whose object is to make it one of the steps by which they gain the portal to the practice of the profession. To all others we leave Nature to give, even from its disorder, such gift of knowledge as it may—with the freedom that is all its own. We strive to follow this example in what we do to help the receiver to receive. But let me remind you that in doing this we cast on you a duty. It is not fit that the institution should be the poorer in making you the richer. The arrangements necessary for you to learn are a constant cost, and the money once devoted to providing the means for teaching which this theatre affords, ought to yield the institution its due—at least, a minimum—interest. This can only be by a response from you by giving to its funds with the same freedom as you must feel in that for which your response is due.

Although the lecture I have the honour of giving you to-day differs from those that will follow it only in being the first, that which begins always seems to possess a certain degree of singularity, even sometimes in a way that involves some vague sense of analogy to greater importance. It is like a capital letter. I avoid saying "initial" letter because this takes our thoughts to the work of the early middle ages, and my only object is to state why I have taken the occasion as an opportunity for endeavouring to expound a general subject rather than explain a special case.

The subject is that which underlies the word "neuron." I do not know what conception you form on hearing the term, but I know what I may safely assume. I shall err only within narrow limits if I assume that, taking you as an aggregate, your conception is a negative one, and that you have no approximately adequate conception of what the word means. Familiar as some of you may be with the subject, it is certain that you have not all an equal knowledge or corresponding knowledge. My only secure course will be to assume the ignorance which Huxley said he had only once dismissed from his thoughts of an audience the most learned, and found he never had made so great a mistake. So bear with me if I thus weary those who do know something of the subject. You cannot know too much, for that which underlies the word is the most important addition to our knowledge of the nervous system, in its physiological and pathological relations, which has been made in the second half of this century—most important in the extent of its application and in the profoundness of its relations.

This revolutionary change in our conceptions is due to the use of silver; to the method of staining which is known as Golgi's method, because first devised in detail by Golgi of Pavia. Although silver has long been used as a stain, this is a method which has not been fully worked out before. It depends on the influence of silver on structure which has been acted on by chromium, and usually also by osmic acid. That which it does is to reveal in hitherto unknown distinctness the course and form of the processes of the nerve cells in the grey matter. These processes, as you know, divide. It has been hitherto believed that they join, and, joining, constitute continuous paths through the grey matter by which the nerve impulses pass from cell to cell, from group to group, and ultimately from one far-reaching fibre to another. And that which this method has shown is that union cannot be traced, but that which is everywhere to be perceived is that these branching processes, "dendrons" or "dendrites," as they are termed, end in the ground-substance or matrix[1] in which the cells lie. In this matrix only the dimmest trace of structure can be seen, and yet there must be an arrangement of its elements.

There is thus discontinuity where there was supposed to be continuity. All nerve fibres, as you know, are prolongations from nerve cells. They belong to the cell and are part of it, so that now there arises before us the vision of a series of discontinuous elements, each consisting of a cell with its processes, and the processes do not join. To each of these elements the term "neuron" has been applied. Yet the nerve impulses pass from one to another; they pass, therefore, by some unseen path through the matrix in which the processes end.

The term "neuron" was first used about eight years ago by Waldeyer, and it has become the universal designation, with a plural not according to the language from which the word arises, but according to the living language of the country in which it is used. We call them "neurons," the Germans call them "neuronen," and the French "neurones." I emphasise this because an attempt has been made to use the word in a more literally accurate sense. You know that there is from each nerve cell an axis-cylinder process as well as many or few branching processes; the branching processes are called "dendrons," and the axis-cylinder process is now termed the "axon." But that is the conspicuous nerve fibre; and since neuron means literally a nerve Professor Schäfer in his books, which are those used in all the elementary schools, uses the word "neuron" for "axon," and he has no other term for the whole cell than "cell." That, as you see, necessarily introduces considerable confusion, and it is an absolutely hopeless attempt to secure literal correspondence—hopeless because the word "neuron" has become established everywhere in a way which makes any attempt to change its use hopeless. I remember Sir William Jenner once saying: "Never attempt to change an established term merely because you can use another a little more accurately." That is wise advice; such attempts are seldom successful, and even if this were successful it is not worth while, for when a definite interpretation has got thoroughly attached to a word it is understood even though it may not be the literal meaning of the term. Where should we be if we were to put into literal language the ordinary terms in use? What a number we should have to discard. We should have to throw away "hysteria" to begin with. A number of other terms have grown up in connexion with the subject which are as yet not firmly settled, so I will give you as few as I can in this outline of the change in our knowledge in order that you may understand its application to disease.

Now, there is in connexion with this, although not directly resulting from it, a second most important fact. The method of staining which I have referred to has also established the truth of an observation made and described thirty years ago by Max Schultze, but ignored almost entirely ever since. You have all learned to regard the axis-cylinder of a nerve fibre as a single thing, a single conducting path. And that great worker whose researches and results have dominated knowledge since those days, Ranvier, did not recognise the truth of Max Schultze's observations, and hence they practically disappeared from current knowledge. But by the study of the axis-cylinder and its divisions by the method of staining to which I have referred, and by other methods which have been elaborated from that, it has been proved that the axis cylinder is a complex structure, each consisting of a number of fibrils. I have searched in vain for any statement of the number of fibrils, but I have been told privately by Obersteiner that in a rather

[1] I do not know that the name "matrix" has hitherto been applied to this ground-substance: some convenient name is needed, and none is yet current.

Digitized by Google

large-sized fibre of the sciatic nerve of a frog there are about fifty of these fibrils making up the axis-cylinder. Each of the fibrils is a separate and distinct conducting path. They seem to be composed of a peculiar material, which is separated by another substance, differing a little, but not enough to enable any distinction to be made out by ordinary methods of observation—for instance, by observing it with the highest power in the fresh state. But they differ (and it is a wonderful thing when you come to think of it) just enough to permit the chemical influence of the hardening agents, supplemented by the effect of staining agents, to act upon them in such a different way as to make them ultimately distinguishable. It is a fact of very profound significance that the slightest conceivable difference in nature, utterly invisible to us, responds to the influence of chemical substances so as to be vastly more observable. I say it is significant because it makes us think of the way in which different chemical substances have an action upon special parts of the nervous system, one substance upon one part and another substance upon another part, although the nerve material at the various places seems absolutely identical. You know the way in which strychnine will pick out certain motor structures on which to act and into which to enter, and you are aware of the way in which atropine will select, of all structures in the body, certain nerve structures in the eye; the way in which lead or arsenic will first enter into and be assimilated only by certain nerve-endings of all the nerve-endings of the body, and so produce special palsy. We see that fact in the effect of poisons during life, which can only be by the way in which the living material must possess some chemical difference, more effective through vitality, by which it is able to receive and react upon, to be changed, and ultimately destroyed, by one chemical substance or compound and not by another. This separating material has a more horny aspect and passes on into the matrix in which the cells lie and there constituting a spongy structure, is called "spongioplasm"; and the material which it separates, which forms these continuous lines of fibrils, as they appear to us, is called the "hyaloplasm," and is apparently the conducting element. There is a sufficient difference between these during life to prevent the passage from one fibril to another of whatever may be the marvellous and mysterious change which flashes along with lightning-like rapidity, and which we call a nerve impulse.

When the axis-cylinder was believed to be a single body we described and believed we recognised its nature; but if we ever perceived its utter mystery we never ventured to emphasise it. I mean the mystery that it divides. The division of a single conducting tract cannot subserve any really intelligible use, except to spread over a larger area its connexions—could serve no purpose such as, for instance, differentiation of sensation. And the number of separate axis-cylinders in the sensory nerves of the skin is not enough to explain the way in which the various forms of sensation are differentiated in the small areas in which they can be distinctly localised,—so much so that one writer, a few years ago, perceiving that fact, denied that there was that differentiation. Because there were not enough axis-cylinders he said there was not the differentiation; that we could not explain the differentiation, nor could we understand the good of the division of the axis-cylinder. But this division we now see to be simply separation of its conducting fibrils. In the light of this fact its service at once becomes clear and the localisation is intelligible. But Max Schultze observed also—and, curiously enough figured it so, although he did not thus describe it in the text—the passage of these fibrils through the nerve cells without any interruption. That has also been securely demonstrated and proved by the new method. So that we have this astounding transformation in that which we perceive; we have in every axis-cylinder a bundle of separate conducting fibrils, and we have those fibrils passing uninterruptedly through the nerve cells to the branching processes and ending at the terminations of their branches. Instead of that old conception of the prolongation of a nerve cell passing to the process of another nerve cell and blending with it, we have the nerve cell receiving a number of fibrils which simply lie together in the process. They may be seen merely skirting the cell body, going from one process to another sometimes, or from several processes to the large axis-cylinder process. From that fact there follows a most momentous fact which is of signal importance to us, and yet which seems imperfectly recognised by those who are working at the subject. Those fibrils passing continuously through the cell body can only conduct through the cell body. Our old conception, so simple, so attractive, that the nerve impulses originate in the cells—fascinating from the analogy of the cell body to a tiny battery originating a current—all that entirely disappears. Moreover, if we find this continuity of the fibrils distinct in some cases we feel at once that it is one of those fundamental structural arrangements which must be universal, and we must once for all give up the idea that the nerve cells are sources of nerve impulse.

What, then, is the function of the nerve cells? We know that on the nerve cell depends the life of the processes; we know how the latter degenerate when separated from the cell and when the cell is destroyed. The cell body is the vital centre for the whole, apparently through the nucleus. A great deal of complex arrangement has been made out in it, but we may disregard this for our present object. The cell protoplasm lessens and then apparently disappears as we pass along the processes, and especially in the long axis-cylinder process. But we find at places some protoplasm, with a small nucleus, and, although it has not been proved, structural arrangements have been discerned which permit the conception that there is a continuity of protoplasm along the fibre, too delicate to be seen, by which the life influence of the cell body is conveyed. So that we have to look at each cell as a vital structure, with its processes and fibres consisting chiefly of the fibrils, but with the life of the whole the fibrils are not directly concerned. They are conducting bodies, elements, which pass through the cell, and the impulses which they conduct from the cell must come to the cell by the branching processes, and they must originate at the extremity of those processes.

How, then, do these impulses arise at the extremities of the dendrons? They arise in consequence of some influence which passes through the matrix from other processes which conduct from a cell; but what happens there is a profound mystery. We have no means of conjecturing whether these impulses pass in some way unaltered through the matrix to the extremities of the other dendrons, or whether some influence which is not the same as the conducted impulse is generated in the matrix. But we conceive that this may be a process of excitation of the fresh impulse—a process which is like a stimulation. We can see that the impulse which arises in the extremities of the dendrons may be excited by something which is not the same, just as an impulse is excited at the periphery by the motion of a touch.

We know really nothing whatever of the actual minute structure of the matrix through which some influence must pass. There appear to be in it the two elements, hyaloplasm and spongioplasm, and yet they cannot be identical in nature with that in the dendrons; the staining by silver of the dendrons disposes of such a view; for the matrix remains entirely unstained. There are other mysteries, but we cannot wonder at that, because if such a vast amount of new fact is presented to us, there must be a corresponding difficulty in discerning details, and the more we can see the more there must always be that we cannot see distinctly.

I think those are the leading facts regarding the new discovery. Let me, however, point out one consideration. At first it seems almost incredible that we should have all these impulses originating in the matrix centres at the extremity of the dendron. It seems intelligible that from the bodies of nerve cells we should have those impulses generated, but it is difficult to understand that all these minute extremities of the dendrons should be capable of generating the nerve impulses which pass with such uniformity and effect along the nerve fibres, each fibre so minute, and yet with fifty fibrils in a single axis cylinder. It is one of the new facts which startle us and the lesson of which at first we find it difficult to absorb. But remember how multiplicity neutralises minuteness. We are apt to forget how the mass of sandstone is composed of those tiny grains which on the beach seem to be so destitute of any element of stability, or momentum, or resistance such as we have in the mass. And everywhere we trace the same fact, from the waves of light downwards. That which is considerable is composed of that which is infinitely small; and I think that with the remembrance of it all difficulty in grasping and holding the new knowledge should vanish. Remember, also, that in the nerve during life all processes of vitality go on with absolutely the same precision, whatever their minuteness or their nature, and also

Digitized by Google

that all the atomic changes from molecule to molecule, by which materials alter and by which energy is made free or locked up, all the changes we call chemical, depend for their precision in the mass for their precision in the molecule.

Let me glance at a few other points; you will be able to discern many in greater detail for yourselves. Consider how this discontinuity explains the arrest of secondary degeneration in the grey matter. You know, for instance, how the ascending degeneration in the spinal cord goes up to the grey matter of the medulla, and the degeneration which goes down the cord stops short of the motor nerve cell, through which, nevertheless, the impulse passes. That has always been a mystery. We had an impulse going down the fibre; we knew it passed through the motor nerve cell; we knew there must be continuity of path, yet why was that degeneration not traceable to the second nerve cell? We could only conjecture that there was a fresh vitality in the nerve cell, which acted along the process a certain distance, and that then the vitality of the fibre was met by the vitality of the descending fibre; part had degenerated, but the part near the nerve cell was preserved. Now we see that they are not continuous; there is no structural unity between them, and we can understand why the degeneration does not pass on into the dendron of the next cell. There is no doubt that the degeneration which results from the destruction of the cell involves the short dendron as well as the long fibre, although the difficulties have hitherto prevented its early observation.

I spoke just now of chemical changes as an instance of the fact that, as of matter so of energy, that which is discernible in amount depends for all its features on that which is minute beyond discernment. Those of you who attend here have heard me say that the chief progress in pathology in the latter part of this century has consisted in the discovery of the immense extent, importance, and profound influence of chemical substances introduced by the morbid processes. The new nerve pathology of this period is chiefly a chemical pathology. It was largely due to the discovery of multiple neuritis, which was found to be almost always the result of a chemical substance. That has been followed by the discovery that when organisms of disease produce effects on the nervous system which are manifested by symmetrical derangement of special functions many of the effects—it may turn out all of them—are the result, not of the organisms, but of chemical substances produced by their growth. And we are discerning now how many poisonous substances are produced—must be produced—in the body by slight modifications of metabolic disorder. That must be the secret of the way in which, for instance, in gout there is now and then sudden evidence of the existence in the body of some acutely toxic agent which may give rise to the perfectly symmetrical effects such as multiple neuritis. Only ten days ago I saw a severe and fatal case of characteristic intense multiple neuritis, which was a result of rheumatic influences in a gouty and rheumatic individual. Instead of the effect of cold being such as to generate a mild poison, by some modification there had been produced that which was capable of acting in a most virulent way upon the nerves. Again, we have the discovery of the way in which the nerves are acted upon by arsenic and other mineral poisons, and we have learned the way in which many other symmetrical results are produced by such mechanisms; how acute specific diseases are followed by such processes in a way that leads us to conclude that the organisms of those diseases must have generated a poison. We are compelled in the same way to believe that locomotor ataxy is the result of some toxic material produced in the body by the syphilitic organisms. It is characteristic that these poisons have a certain proclivity to certain parts; and in locomotor ataxy we find that the degeneration occurs in two parts—in the fibres which conduct towards the cord and in the posterior median columns. We have the strongest reason to believe that the fibres in the posterior median columns are the continuation upwards of the afferent paths from the muscles. Both of those belong to the nerve cells of the posterior ganglia; they are dependent on those cells for their life, so that those fibres, with the cell, constitute a neuron. Thus we see that tabes is a degeneration of a single neuron, and we know that just the same degeneration is produced by some actual poisons. Hence, that which we call a disease, which we recognise by changes rather widespread in the system, is simply the illustration of the affinity of a poison for one definite nutritional unit. Another most interesting point which we conceive and understand so much better in the light of the new facts is the strange circumstance that in paralysis agitans we never get structural degeneration of the motor path, although we are compelled by all facts to regard it as a senile degeneration of the motor cortex of the brain. I have not time to describe the evidence of that, but senile degenerations when intense tend to go on to decay and death of the parts, and it was a mystery why we do not get such degeneration in paralysis agitans, and why therefore we never get in that disease, in spite of the peculiar spasm, a foot clonus. One would think it was the symptom which, of all others, would be there. It is absent because we do not get degeneration of the pyramidal fibres in the disease. But we see that the spasm and rigidity must be the result of charges at the place at which the impulses arise—namely, in the extremities of the dendrons. When we thought of the motor impulses coming from the nerve cells we thought the degenerating processes must be in the nerve cells, but, you see, all we are justified in doing is to refer the morbid processes to the extremities of the dendrons, and the nutrition and vitality of the dendron depends on the cell body. It ceases to be surprising; and it also ceases to be surprising that all search for morbid changes in the nerve cells has been in vain.

But there is one great test of the truth of our ideas, and by "truth" I mean the correspondence of our thoughts with the facts they represent to our minds. That test is the revelation of correspondence where there seemed to be diversity. Those things that seemed dissimilar and yet ought not to be according to our general knowledge are seen to be alike from our new point of view. What is even more important—so important that I shall have to ask you to note how our subject illustrates it—is that things that are far apart are seen to correspond. I will make this clearer in a moment. I think it would not be easy to find in physiological and pathological science anything more striking than the fact that this origin of the nerve impulses at the extremities of the dendrons brings into harmony the functions of the elements of the nervous system, central and peripheral. We now see in the centre the same isolated, separate, minute multiplicity of origin and subsequent blending that we find and are familiar with in the periphery, in the way in which the sensory nerve impulses originate at the terminations of that which we thought to be the divisions of an axis cylinder and now see to be the extremities of its component parts. Compare this with the quite diverse aspect of such an origin of the nerve impulses at the periphery and in the bodies of nerve cells in the centre. I repeat this because discoveries that involve normal correspondence not only are testimony to truth, but prepare us for perceiving corresponding morbid changes the discernment of which may be to us a revelation. Take this example, not unrelated to our present subject. We have taken a step upwards and onwards when we perceive that primary lateral sclerosis is a degeneration of the fibres of the pyramidal tracts, which begins at their terminations in the grey matter, in the ramifications which terminate the axes of the fibres, and conceive of this as a degenerative process, similar in all essential relations of seat and nature to the degeneration in the peripheral fibres with which we have become familiar as degenerative peripheral neuritis. In each case we have the failure of nutrition in the extremities of the fibres, of the long processes the ends of which are far distant from the vital centres. It is known that the degeneration of the pyramidal fibres in its early stage is greatest below and may even cease a short distance up the cord, precisely as does that of the fibres of the limbs. We see this analogy, and more than analogy, with far more clearness if we perceive also the termination of the branching ends of these fibres in the matrix of the grey substance of the cord, just as those of the peripheral nerves terminate, for instance, in the skin. Here we have another definite extension of that which we must call knowledge in consequence of the discoveries we have been considering.

The difficulty of readjusting our thoughts seems even greater if we look at such diseases as epilepsy in the new light. We have to conceive the sudden energetic discharge with all its simultaneity, with no appreciable interval between that which occurs on the two sides of the brain, to be from this infinite multiplicity of motor dendrons. It is enough to make us recoil from the new conceptions and look back at the old, and at the path we have traversed, to see

Digitized by Google

whether, after all, we can have been right in the steps we have taken. But we now perceive in the old conceptions the same difficulties that we have in the new, though we never before realised their existence. We find it no easier to conceive these impulses arising from the nerve molecules of the cells than from those of the dendrons. We have simply the same elements, the minute masses of nerve substance, which are compactly arranged in the cell body, separated at the ends of its processes. It is as hard to think of the action of such groups, simultaneous or successive, combined or disjoined, if they are massed in a nerve cell as if they are at the ends of the short processes, separated by distance that is unimportant and, moreover, accessible far more readily to the nutritional material the molecules of which bear in their mysterious constitution the hidden energy to renew that lost in function. There flashes upon us, as it were, the fact that we had been blinded by ideas which seemed to have in them a capacity of explanation wholly illusory. And it seems as if the perception we have got of the extension of the nerve structures is a symbol of the extension of our thought; we are able to see, at least dimly, through that which was before obstruction, and if we can discern but little more by seeing through, it is nevertheless a real advance to be able to discern light where before there was darkness, though it be only light.

All such facts as these, gentlemen, are not merely general and to some extent theoretical; they are essentially practical. For they enable you to form more clearly and more adequately that visual picture of the disease which is before you, the ability to construct which can be cultivated and increased so much by use and practice, and which enables a man to obtain a much more clear conception of what there is in the individual case before him, to forecast more accurately its future course, and to discern with more precision by what means that future course may possibly be modified. The picture we can form of all the fine diseases of structure and of the way in which function is deranged when molecular nutrition is altered or toxic agents act—arrest, augment, or alter—this is made different by the new view we have to take. To make it useful we must become familiar with its details; we have to become able to recognise old facts under a new aspect. In all that is novel difficulties loom large, and use and wont, with the time they need, alone can enable us to gain in power from the gain in knowledge, and to secure that increased service which lies before us, not altogether hidden, and yet quite inadequately perceived.

An Address
ON
THE ARMY MEDICAL SERVICE.

Delivered to the Students at the Opening of the College Schools on Nov. 1st, 1897,

BY SIR WILLIAM THOMSON, M.D. R.U.I., F.R.C.S. IREL,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

LADIES AND GENTLEMEN,—In inaugurating to-day the winter session of your studies I have to repeat on behalf of the council, the professors, and myself our most cordial welcome. If these words are trite I ask you to believe that they are very sincere—for to us who are your seniors it is always a pleasant duty to meet generation after generation of our younger fellow students who are setting out upon the path which we, too, have trod. Days like this may tell us that we are growing older, which is not a pleasant reflection; but they bring back to us the memory that we, too, had a beginning of study as you have; that we were filled with all the hopes and legitimate ambitions which I trust inspire you; and that we made our youthful resolves, as I beg of you to make them to-day, to strive with all our might to do our duty in the world.

The school which you have joined is one to which you may well be proud to belong. It has had a long and illustrious life. Out of these halls have passed crowds of men who have gone into all the corners of the earth doing credit to the fair name of their country, and upholding, as the phrase of the declaration of our Licentiates goes, "the honour and dignity" of our College. Among many others there occur to me at this moment three or four who have become exceptionally distinguished. One is our countryman, Sir William MacCormac, who at the present moment fills the Presidential Chair of the Royal College of Surgeons of England, and on whom Her Majesty has recently conferred a baronetcy, a man known the world over for his splendid attainments. In Australia Sir Thomas N. Fitz-Gerald, the leading surgeon of Melbourne, stands alone in that country as the first medical recipient of a Royal distinction. In India the principal medical officer of the army is Surgeon-General Gore, whom so many of us know and value so highly; and in Ireland to-day the Army Medical Department is presided over by our friend, Surgeon-Major-General Preston, who, like his comrade, bears honourable wounds received on the field of battle. The school to-day is, I am glad to say, full of the energy and vigour which are so necessary to success, and I am very sure that if you will only take advantage of your opportunities there are open to you all the rewards which are to be earned by absolute devotion to the work of your profession.

But let me say that this school has not a monopoly of excellence. The other medical schools of Dublin and of Ireland at large are all animated by the same desire to excel—to turn out the student fully prepared for the labour of his life. Whatever rivalry exists is not a parochial one. I trust we all cling to the school in which we were taught. We like to revert to our early associations with it, to watch the career of our companions of those days, and to rejoice when we see some new glory added to its name. I do not care much for the man who, without some very special cause, does not stand up for his school or college or university. I like him to think it the best. I like to know that his young and generous affections have fastened themselves upon the place where his early thoughts began to develop and were shaped for the career which he has chosen. Therefore I hope you will stick up for your school. But I should like you to remember that for the outside world there is even a higher ground upon which you may stand. You may belong to this college or that University, but you are students above all of the Irish Medical School, and in that fact you may well find a power to evoke your pride. It has a record which is one of the brightest of this land, and it has helped in no small degree in the past, as it does now, to create and to mould the modern teaching of medicine and surgery. I congratulate you on belonging to it, and on holding the belief that you can find at home teachers as zealous and as learned as are to be found in any other part of the whole kingdom.

Last year when I had the honour of addressing you from this chair I endeavoured to impress upon you the advantages which members of our profession must derive from a liberal education, and I tried to interest you in the cultivation of general literature as a relaxation from the severer work in which you will be engaged. To-day I intend to occupy a short time in dealing with one or two matters which more nearly affect the actual study in which you are embarked.

I think I may assume that all of you have already begun to think of what you will do when you have passed your final examination. Some of you will probably pass into the struggle of civil practice with its great possibilities and great uncertainties. Some of you look forward to the public services, which have the advantage at all events of security of income with a fair share of honours. You cannot, therefore, fail to be interested in the agitation, which seems to arise with almost rhythmical regularity, concerning the Army Medical Service. You are, of course, aware that at the examinations held in August last candidates to fill thirty-six places were advertised for, and that only twenty-two presented themselves, and that in February last there were thirty-five vacancies and only twenty-six candidates, of whom but thirteen qualified to enter the service. In the two preceding competitions practically the same state of things existed. The result is that at the present moment there are over eighty places vacant—places which cannot be filled. That is a very startling fact, because in some respects the Army Medical Service offers a splendid career to a young surgeon. It has its risks of course, but a man who enters it must accept them, and we know that they have not in former times prevented some of the best of our Licentiates from joining. In a monetary sense it far exceeds the combatant branches. In addition to better pay it is possible for a man to leave the service after twenty years with a pension of a pound a day, and so on, in proportion

Digitized by Google

to time. Compared with the ordinary results in civil life this is a very exceptional position, and therefore the dissatisfaction which has led up to this abstention of candidates must be of a serious character. Several commissions have sat to take evidence as to these grievances, and warrant after warrant has been issued yielding certain claims. But a number still remain unsatisfied. I do not propose to occupy your attention with these in detail, but I shall shortly refer to one or two that stand pre-eminent.

The primary grievance is a question of rank, and here we find the views of the combatants and the surgeons directly at variance. The medical officers declare that although they are styled Surgeon-Captains and Surgeon-Majors, and so on, these titles give them no real rank whatever in their relation to other officers and men of the army, and that they are constantly subjected to humiliations which make their position unbearable. The rank is a departmental rank; that is, they are Surgeon-Captains within their own department, and it is alleged that the other officers make this difference felt in such a way that the example set is followed by the rank and file. Indeed, at the Camperdown Commission of 1890 one very distinguished general officer said he addressed the head of the Army Medical Department as "W. MacKinnon, Esq., C.B., Director-General Army Medical Staff," although the title to which that gentleman was entitled was "Surgeon-General MacKinnon," and he was marked in the Army List as "ranking as Major-General." Now it may be supposed that the army surgeons have only to do with the sick in hospital, and the wounded on the field. But they have actual military duties to perform. They have under their direction a body known as the Medical Staff Corps, which is composed of bearers and male nurses, and, generally, of the men who aid in rescuing the wounded, and carrying all the equipment of hospitals on the field. These men are drilled by medical officers and marched into action by medical officers. The position of civilian Mr. John Smith, Surgeon, then, in command of a disciplined bearer company, would thus be rather an anomalous one.

The case on the opposite side is that medical men in the army have only rank in their own department, and that to give them real rank in the army, or to call them after the form of "Captain Smith, Surgeon," would be to place them in a ridiculous position. It has even been unwisely alleged that if this plan were adopted a case might occur in which a medical officer would take the command of the combatants in the event of the officers above him being disabled. As a matter of fact such a thing has happened, when all the Combatant officers were wounded; and you will be glad to hear that the surgeon, an Irishman, and a Fellow of this college, led his men to victory and was promoted for it. But no one has ever made such an absurd claim as that of combatant command. Moreover, in other corps officers who are given rank have what is called limited command, that is, only over the men in the special body to which they belong. Therefore, there is no force whatever in the objection to which I allude, and it appears to have been made without knowledge of the laws of the service. But we have examples in other countries of how the system works. If we take Switzerland we find a citizen army which is turned out every year for a month's training. It is put on war footing to carry out the manœuvres. I am assured that there are many things in that army which we might copy with advantage. But there we find the private practitioner summoned to his duty as a military surgeon. He at once becomes captain or colonel, as the case may be, and after his labours are over he reverts to his old position and assumes his civilian title once more. His distinguishing mark on the field is the Geneva Cross on his arm, and no one thinks of his being mistaken for a combatant.

But it may be further stated on behalf of the army surgeons that they are the only officers who are denied the simple title of their rank. The captain of Engineers is not called Engineer-Captain, but Captain, Royal Engineers; nor do we hear of Paymaster-Colonel or of Army Service Corps Major. The officers of the Army Service Corps are now Majors, Captains, Lieutenants, and the same titles are extended to the pay department and to some army schoolmasters. There are no prefixes to dilute the rank. As to the Pay Department the answer is made that the officers have already attained rank as combatants. That I admit. But I reply that they have resigned their positions as combatants and can never go back. They have passed into a branch which is purely civil; they certainly have not to discharge their duties under fire; but still they continue not only to hold these titles but to pass on step by step until they receive the title of Colonel. It is true also that some of these are honorary only, but they have a distinct social significance, and they serve to show that there is a liberality in the extension of these advantages to other departments which is refused in the case of the medical department. Let me say at once that I am trying to bring before you some points in the case made by the medical officers. I see certain difficulties in the way, but then I must remember that we are looking at the whole matter from a standpoint outside the army. We cannot understand the thousand and one matters which cause friction as do the men who spend their lives in the service. All we can say is that more than three-fourths of the medical officers claim army instead of departmental rank, that they are in the best position to judge of the importance of this concession, and that the solutions of the difficulty which they propose are based upon experience.

A second claim which is made is that the whole of the medical service should be converted into a Royal corps. The arrangement which at present exists is a curious one. The surgeons form a body which is called officially the Army Medical Staff. All the men who constitute the bearer companies and male nurses, and who are concerned in general hospital work, whether in the field or at stations, are called the Medical Staff Corps. In other words, the officers are in one group and the men are in another, and they do not even wear the same uniform. If this plan were carried out throughout the army we should have an extraordinary condition of things, for the combatant officers would be nominally separated from the soldiers whom they had to command in action. The necessity of having the whole medical apparatus—if I may so call it—of the army formed into one body is obvious. In these days the succour of the wounded is one of the most important obligations which attach to the general conducting a campaign. Organisation and a perfect technique are indispensable if the maimed are to be rescued quickly and successfully treated. The men who have to do this work should be under the sole direction of officers whose training fits them for that position. For really efficient work it is essential that these two bodies should be formed into what is known as a unit. In this way the men know their officers and the officers their men. In a united corps the surgeons would soon judge the quality of their subordinates, their proficiency, how far they could be relied upon in difficulty, and all the advantages which arise from the daily contact of commander and men. If such a body existed it would be possible to improve the internal defects which now exist in the medical department itself and to place it on a higher level of efficiency by a system of continued professional education. But at present the officers and the men are in two separate groups. They are moved about independently of each other; and when an emergency arises so many medical items are suddenly thrown together to settle down as best they may. It is very much as if in the case of a battery of artillery a number of officers, gunners, and drivers who had never met before were sent to take charge of guns that they had never fired, and horses they had never ridden, and were bundled into action at once. If this strange separation is good, why does it not prevail in the Royal Engineers or other departments? But it would be destructive of that pride which every soldier feels in the branch to which he belongs. The medical officer, then, naturally anxious that his department should be kept at the highest standard of efficiency, asks to have the present system of dual bodies abolished, and by the creation of a Royal Medical Corps to establish that cohesion and *esprit* which unity alone will give.

There are other matters of perhaps smaller importance which I will not discuss, but in their aggregate they have served to create a discontent among army medical officers which has culminated in the present condition. I know that the combatant branches of the army declare that they wish to have good surgeons, and that they would be glad to remove any causes of complaint. But they are unanimous on the question of rank, and they will not yield upon that point. I have said already that we are only outsiders, but I think we are able to say from what we see that that demand is crucial. Whatever is done the rank which is given to the medical officers must not be a mere departmental name, but a real rank which will secure them from the petty indignities to which their position subjects them. The present rank means nothing, and the medical officers have learned to understand that they are only civilians in the eye of the army. Nothing, I think,

Digitized by Google

could have been more unfortunate than the application of this term. It has been made free use of and it has served to establish many in their hostility to the medical officers. But are they civilians? They hold commissions in Her Majesty's army, they wear a uniform and carry arms, and in an army they are placed in charge of the thousands of armed men and the transport which go to make up a hospital train. In action they are with the fighting line. Of necessity they are where the fire is heaviest, for their duty is to relieve the wounded on the spot where they fall, and for this reason you will realise why it is that the death-rate of army medical men is nearly twice as great as that of the combatant officers. I looked into the Army List the other day and I found that nearly twenty surgeons who are actually serving or are alive and retired have won the Victoria Cross. And I noted also that they are called "military recipients" of this splendid reward "for valour in battle." If they are "military" they are not "civilian." I press my argument further by pointing out that no civilian can win the decoration. The Victoria Cross warrant expressly declares that the Cross is for the naval and military services only, and that no "other circumstances or condition whatsoever, save the merit of conspicuous bravery, shall be held to establish a sufficient claim to the honour." What, then, becomes of the allegation that army medical officers are only civilians? They are not only in the army, but they are of the army. Every circumstance of their official lives proves it, and there will be no contentment until that fact is established by warrant beyond all cavil.

I have brought these matters before you so that you may understand some of the reasons of the outcry which is raised against the Army Medical Service. Even with these drawbacks many will find it to their interest to go forward for appointments. I by no means blame them. The competition of life is very keen, and I do not advise anyone to hold back. Perhaps I shall be condemned for this statement, but who, I ask, will provide an equally secure position for the young men who follow counsels of another kind? I know of none; and it seems to be asking too much of our students to stand back and thereby perhaps sacrifice a life's career. Each knows his own necessities and desires. We will do all in our power, as we have done, to help forward army medical reforms, but we must not speak hardly of those who in spite of disadvantages seek entrance into the service. At the same time the authorities must know that many brilliant men are looking elsewhere for a career, and that it depends upon an enlightened policy whether the medical department of the army will be again largely recruited from among the most promising of our young surgeons.

I pass from this question of the day to congratulate the prize-winners. Mr. D. A. Fitzgerald and Mr. F. J. Palmer have been awarded the Carmichael and the Mayne Scholarship respectively, and having regard to the extent and severity of the course their success is a brilliant one. In the classes Mr. J. S. P. Stewart has won three firsts and a second, and Mr. E. Glenny two firsts and a second, a result which points to still higher distinction in the future. Then Miss Dreaper and Mrs. Hennessy have each carried off a first and a second prize, and thus illustrated the fervour with which our lady students devote themselves to their work. The rest of the list shows that a large proportion of the class has engaged diligently in the studies of the various years, and it is a special gratification to find that in every instance a candidate has qualified for a first rank. Of the number who just failed in the struggle I have no record, but I wish to encourage them and all others to try again. They must not take defeat to heart too keenly and throw down their hands in despair. I have known some distinguished men who never could win a school prize, although later they earned the highest successes in life; and I trust that some of you who miss your names from the returns will yet achieve that which you have lost to-day. There is much that I should like to say to you now, for next year another President will speak to you from this place; but time is running out and I have already trespassed upon your indulgence. But I should like you always to bear in mind in your work that examinations are not the only things for which you should read. To have in your mind constantly that you must only make up what will get you through the portal is demoralising; it begets the worst of all mental processes—cramming. Prepare for your examination by all means, but let your reading be wide and generous. And, next, I sometimes feel that students do not value as they ought the work in the hospital wards. Give to this all the time you can spare, not with your hands in your pockets, as I occasionally see, but with your mind keenly set upon the cases which are before you. For, necessary as all teaching in the schools is, and important as it is that you should be highly informed in the subjects taught here, it is with the living sick you will have to deal when you come to practise. No amount of knowledge will avail you unless you can apply it—unless you are able to recognise disease or injury and use your remedies. In a very few years these classes which I now address will have passed away into the world. You will be scattered here and there; some in large cities, but many in places where you will be isolated from the helping mind and hand of a member of your profession. Then you will realise in its fullest extent what responsibility is—what it means to have in your charge a case which you find difficult to read and which you must deal with alone. Nothing will be more distressing to you than this failure to help if after all the fault is your own. I ask you, therefore, to try to realise that responsibility now before the day of humiliation comes, and by your industry to relieve yourself of the possibility of self-censure.

With these words I draw to a close, only waiting to assure you that your teachers will do their part, that we all wish you the highest success, and that we shall look to you with confidence to uphold the reputation of the medical school of this old city of Dublin.

SOME NOTES ON OVARIAN TUMOURS, WITH A FIRST SERIES OF FIFTY OVARIOTOMIES.[1]

BY WILLIAM JOHN GOW, M.D., M.R.C.P. LOND.,
PHYSICIAN-ACCOUCHEUR TO OUT-PATIENTS, ST. MARY'S HOSPITAL; OBSTETRIC PHYSICIAN TO THE ROYAL HOSPITAL FOR WOMEN AND CHILDREN AND TO THE METROPOLITAN HOSPITAL.

THE remarks contained in this paper are mainly founded on a series of fifty cases in which I have performed the operation of ovariotomy. The term "ovariotomy" is used to indicate the operation for the removal through an abdominal incision of cystic and solid tumours of the ovary, and also the operation for the removal of parovarian and other broad ligament cysts. No case is included where the ovaries were removed for the purpose of checking the active growth of fibroid tumours or where the appendages were removed on account of salpingo-oöphoritis.

It is well known, though none the less remarkable, that in many cases no symptoms other than those of enlargement of the abdomen are complained of by women who are the subjects of ovarian or broad ligament tumours, and that it is on account of this enlargement alone that they generally present themselves for treatment. Symptoms are, however, by no means always absent. Among my own series of cases disturbances of menstruation were the commonest of all symptoms and were noted in eleven instances. In three of the cases there was amenorrhœa for a longer or a shorter period, and in eight cases there was menorrhagia or metrorrhagia which appeared in point of time, as far as could be judged, to correspond to the growth of the tumour. It did not seem possible to attribute the alteration in the menstrual function to mere coincidence, but I had previously believed that an ovarian tumour, if it affected the menstrual flow at all, more often led to its cessation than to its increase. The history of the cases here recorded, however, does not support this view.

So far as it is possible to judge there does not appear to be any connexion between the variety of tumour and the nature of the change in the menstrual function. It has been asserted that with fibromatous tumours of the ovary menorrhagia is common, and in the single case of fibroma of the ovary which I have operated on menorrhagia was certainly present. The co-existence of amenorrhœa with the development of an ovarian tumour often leads the patient to believe that she is pregnant and may even mislead the medical attendant unless a careful routine examination is made. One of my patients, who was a single

[1] A paper read before the Harveian Society on Jan. 7th, 1897.

Digitized by Google

woman, not only believed that she was pregnant, but had even succeeded in identifying the supposed father, and was up to the time of operation in receipt of a weekly allowance which had been granted to her as the result of legal proceedings. It is probably the only case recorded in which an ovarian cyst has proved to be a source of income. It is much more common for a gravid uterus to be mistaken for an ovarian tumour than for an ovarian tumour to be mistaken for a gravid uterus, and although in many cases it is hardly possible to make such an error, yet in some cases the differential diagnosis is not made without a good deal of trouble. If a well-marked fluid thrill is present the idea of pregnancy may practically be put out of court at once, but it is not uncommon for an ovarian tumour to resemble very closely the consistence of a gravid uterus at the fifth or sixth month, and secondary cysts projecting on the surface may easily be mistaken for fœtal parts. Fœtal parts, however, move away from beneath the fingers of the examining hand, whereas the projecting knobs of the ovarian cyst remain permanently in the same place. Of course, in many cases a careful bimanual examination will reveal the unenlarged uterus lying apart from the tumour, but some broad ligament tumours and tumours which have formed adhesions to the uterus move with the cervix. A careful consideration of the history of the case and a thorough physical examination will rarely leave any real doubt as to the diagnosis. In cases of doubt it is always better to wait for one or two months rather than run the risk of opening a patient's abdomen and finding nothing but a gravid uterus. Menorrhagia and metrorrhagia seem to be about equally common, but it is very rare to see the loss sufficiently profuse to induce any marked degree of anæmia. The removal of the tumour has always led to the disappearance of this trouble, and this supports the view that the occurrence of menorrhagia or metrorrhagia is not a mere matter of coincidence.

Pain is another symptom which is fairly common, and sometimes is very difficult to account for. Twisting of the pedicle or suppuration and inflammation of the cyst, of course, are well-known causes, as is also rapid distension of the cyst from hæmorrhage into it, but in several of the cases recorded very severe pain was complained of and yet at the time of the operation nothing could be discovered to account for it. In one case, a girl, aged twenty-five years (Case 31), who had a parovarian cyst on the right side reaching to two inches above the navel, severe paroxysmal attacks of pain were complained of which were sometimes so acute as to induce fainting, and yet at the time of the operation there were found to be no adhesions nor any evidence that the pedicle had ever undergone torsion. This shows that the occurrence of intense abdominal pain in a woman with an ovarian cyst does not necessarily mean that the pedicle has become twisted, or even that there are necessarily any adhesions between it and adjacent parts. In several other cases symptoms of a very similar nature were observed, for which no very definite cause could be discovered at the time of the operation. It seems probable that these attacks are of a colicky nature, and are due to irregular intestinal contractions caused by the presence of the tumour. Attacks of paroxysmal pain of a similar nature were a prominent symptom in a patient of mine who suffered from fibroid tumours complicating advanced pregnancy, and in her case sickness and some degree of constipation usually accompanied the onset of the pain, thus suggesting its intestinal origin.

Another condition which can hardly be spoken of as a symptom, but which sometimes is associated with the presence of ovarian tumours, is procidentia uteri. Complete procidentia in young virgins is undoubtedly a rare condition, but in six cases of this nature which I have myself seen in three of them ovarian tumours were present. This would certainly seem to indicate that there is some causal relation between ovarian tumours and procidentia, and shows how important it is in all such cases to make a thorough abdominal examination in order to determine if any ovarian new growth exists. In the cases which have come under my own notice the tumours lay above the pelvic brim, so that they could at that time, at any rate, exert no direct pressure on the pelvic floor, although of course when smaller they might have done so. This fact seems to suggest that if the procidentia is more than a coincidence it must be due to altered pressure relations within the abdomen, which would no doubt be more easily produced in young women with firm, resistant abdominal walls than in older women whose abdominal walls had already been stretched by child-bearing or weakened by the use of corsets. My youngest patient in whom procidentia was associated with the development of an ovarian cyst was fifteen years old. When first seen both anterior and posterior vaginal walls were completely everted, the cervix forming the central portion of the mass which lay outside the body. After ovariotomy she still had to wear a small ring to keep the anterior vaginal wall from bulging downwards, but before the operation no instrument could be retained. The tumour in this case lay in the abdominal cavity above the pelvic brim and did not extend into it.

Suppuration of an ovarian cyst is always the result of infection with pyogenic organisms. The infective agent may reach the interior of the cyst by one of three routes: (1) the lymphatics; (2) the Fallopian tubes; and (3) the intestine or vermiform appendix. Among my series of ovariotomies I met with four cases of suppurating cyst. Some authorities hold that by far the commonest route for the pyogenic microbe to take is the Fallopian tube. But in two of my cases the infection had certainly not reached the interior of the cyst by this way because in one of them the corresponding tube was perfectly healthy and in the other it was converted into a hydrosalpinx, which was not adherent by any part of its surface to the ovarian cyst, but was connected with it by a distinct and healthy mesosalpinx. In both of these cases the intestine was closely adherent to the surface of the cyst, and it seems therefore probable that the micro-organisms had passed from the interior of the bowel to the interior of the cyst, although in one case the suppuration dated from childbirth—or, at any rate, since that time the patient had suffered much pain in her tumour and had emaciated very markedly. No bacteriological examination of the pus was made, and therefore no absolute proof can be offered that the intestines were the source from which the infection was derived. In another case (Case 44) the suppuration was induced by a vaginal operation which had been performed six months before, apparently for the purpose of removing a uterine polypus, the operation being followed, according to the patient's account, by high fever and delirium, which lasted many weeks. In this case the pyogenic microbes probably reached the cyst through the lymphatic vessels or Fallopian tube. It is perhaps worth noting, but probably is a mere coincidence, that all the cysts which had suppurated lay on the right side. In three out of the four cases there was no rise of temperature, but in three of them there was marked emaciation. The pus contained in suppurating ovarian cysts is generally found to be sterile—that is to say, it contains no living micro-organisms, although they may be met with in the walls of the cyst; and this fact is one of considerable importance because it explains, what is well known practically, how if some of the pus escapes and soils the peritoneum there is very little real danger of septic peritonitis developing.

In four cases the cyst had ruptured. In two of them the rupture was the result of direct violence, and in the other two it occurred spontaneously. In the first case the patient, who lived in the country and was known to have had an ovarian tumour for eight years, fell out of a cart and alighted upon her abdomen, which was the most prominent part of her body. When seen by her medical man a few hours later she was found to be suffering from symptoms of collapse and complained of considerable abdominal pain, and the tumour, which was previously a very large one, had become much smaller and less well-defined. She remained in bed for six weeks. The tumour, however, soon began once more to increase in size, and four months later she was sent up to the Royal Hospital for Children and Women, and I removed a large very adherent papillomatous cyst of the right ovary. The omentum had to be extensively resected before the tumour could be drawn out.

In the second case (Case 33) the tumour, a dermoid, was ruptured during delivery. The posterior vaginal vault was also torn through, opening up Douglas's pouch, so that most of the greasy contents escaped externally. The collapsed cyst was removed by abdominal section on the fourth day of the puerperium. Spontaneous rupture of an ovarian cyst was observed twice in the same patient (Cases 39 and 50). On the first occasion a large multilocular cyst of the left ovary was removed, and on opening the abdomen the peritoneal cavity was found to contain a quantity of extremely thick gelatinous material which had escaped from one of the locules. The cyst wall was remarkably friable and tore with great ease. The peritoneum covering the intestines was

Digitized by Google

found to be deeply reddened and roughened so that it looked like velvet pile. Eight months later a second operation had to be performed owing to the development of a similar tumour in the right ovary, although this organ when examined at the time of the first operation was observed to be in no way enlarged. In this instance also the cyst had ruptured spontaneously and a large quantity of ovarian fluid was present in the peritoneal cavity. On neither occasion were there any special symptoms indicative of the extravasation of the cyst contents. I have already alluded to the question of the differential diagnosis of ovarian tumours from intra-uterine pregnancy, but the diagnosis of ovarian tumours from uterine fibroids, though sometimes easy, is, on the other hand, sometimes impossible, and this illustrates the importance of never undertaking to perform an ovariotomy without being prepared to perform abdominal hysterectomy if the tumour turns out to be uterine instead of ovarian. Until lately I had always thought that the presence of a souffle was distinctive of a uterine tumour of some sort, but in one of my cases (Case 42) on which I operated last summer a very highly-marked souffle, identical in character with that which is heard over a gravid uterus, was audible all over the abdominal tumour, and yet when the abdomen was opened it turned out to be an ovarian cyst occupying the left broad ligament. The tumour was not unusually vascular and no great vessels were seen running across its surface, and the only way in which I could account for the presence of the blowing murmur was by supposing that the sound originated in the aorta or iliac vessels owing to their being pressed upon by the tumour and was thus transmitted to the surface of the abdomen. The error in diagnosis—for I believed it to be a fibroid—was rendered more easy to make by the fact that the tumour filled the whole broad ligament and ran close up to the uterus, so that tumour and cervix moved together as one mass. Soft myomata which project from the surface of the uterus to one or other side of the pelvis, whether sessile or pedunculated, may be mistaken for ovarian cysts, and no amount of examination will sometimes prevent an error in diagnosis.

Another condition which may easily be mistaken for an ovarian tumour is extra-uterine gestation. Only a few days ago I operated on a woman who had what I thought was an adherent ovarian cyst lying in the pelvis behind the uterus but found on opening the abdomen that I had to deal with a tubal pregnancy of three months' development. In this case there was nothing in the previous history to suggest the true nature of the tumour which was felt. On another occasion a middle-aged woman presented herself with a hard irregular tumour in the left iliac fossa which was diagnosed as an ovarian dermoid. At the time of the operation it turned out to be an old six months' extra-uterine gestation which was encapsuled, and had evidently long since ceased to develop. The condition of the fœtus and sac, and the history subsequently obtained from the patient seemed to show that the gestation must have originated some two or three years before. In most instances, however, a careful consideration of the history and physical signs enable a differential diagnosis to be made; but in some exceptional cases like those above alluded to a correct diagnosis is hardly possible. One case at least (Case 39) merits a more detailed consideration because of certain points of unusual interest connected with it. The patient, who was sixty-three years of age, first came under observation in March, 1896, on account of a lump in the abdomen which had been noticed for five or six months. She had suffered, and was still suffering, from well-marked diabetes accompanied by emaciation. This disease seemed to have started about five years before, and at one time the symptoms were extremely serious, but under the influence of a rigid diabetic diet they became considerably less urgent, although she still continued to pass sugar in the urine. The abdominal tumour was very hard and nearly fixed and reached up to the navel; it was not tender and there was no ascites. It was feared that the tumour was malignant, but an exploratory operation was advised, although the existence of the glycosuria obviously increased the risk of such a procedure. At this time the amount of sugar passed was about eight grains to the ounce. The patient, however, did not come up to town for another two months, and during this interval the tumour grew rapidly, and now reached up to the ribs. The abdomen had become much more prominent, and the patient complained of considerable discomfort, and was only able to get about with great difficulty. There was at this time distinct evidence of free fluid in the peritoneal cavity. The urine contained sugar as before. Sir John Williams saw the patient in consultation with me, and it was decided to perform an exploratory operation. A week later I therefore operated upon her, and on opening the abdomen found that the peritoneal cavity contained a large quantity of thick colloid fluid which had been poured out into it as the result of the rupture of one of the compartments of a multilocular cyst of the left ovary. The tumour itself was non-adherent, and consisted of a large number of small cystic cavities containing a jelly-like material. This was scooped out and the tumour removed. The peritoneal cavity was cleansed as thoroughly as possible by means of irrigation with hot water. The right ovary was examined, but as it was quite small it was not removed. The patient made a good recovery. During the first week after the operation the urine passed was of very low specific gravity, and no sugar could be detected, but during the second week the sugar reappeared.

The hardness of the tumour was due partly to the extreme thickness of the fluid and partly to the large number of cavities in which it was contained. About four months after the operation the patient noticed another tumour in the right iliac fossa. It continued to grow, and when seen in February of this year there was a firm mass the size of a man's head occupying the right half of the abdomen, lying well above the pelvic brim. On opening the abdomen for a second time (Case 50) a tumour was found originating in the right ovary of a precisely similar nature to that of the left ovary, which had been removed eight and a half months before. The peritoneal cavity on this occasion also contained a quantity of colloid material which had escaped from the tumour, and it was necessary to again resort to irrigation to get rid of it. The patient once more made a perfectly uneventful recovery. I know of no other recorded case where ovariotomy has been twice successfully performed on a patient who was the subject of diabetes. On the second occasion the urine was tested and showed the same amount of sugar as before.

Dr. Halliday Croom, in the "British Gynæcological Journal," February, 1896, relates the case of a woman on whom he performed ovariotomy who at the time of the operation was the subject of glycosuria. According to him very few cases of ovariotomy in patients with diabetes or glycosuria have been reported, and but little is known as to the risks of operating under such circumstances. In Dr. Croom's case there was no thirst, polyuria, or emaciation, and the glycosuria seemed to have developed since the appearance of the tumour, and certainly disappeared a few weeks after its removal, and Dr. Croom believed that the tumour caused the diabetes, possibly from irritation or pressure upon the pancreas. The case which I have related above is interesting, not only on account of the fact that the patient was suffering from diabetes at the time of the operation, but also as an illustration of the difficulty of being sure whether an ovarian tumour is malignant or not. Hardness, lack of mobility, rapid growth, and the presence of ascitic fluid may all prove misleading, so that in every case in which there is the least room for doubt an exploratory operation should always be undertaken. An incision sufficient to admit two fingers is often all that is necessary, and if on examination there is clear evidence of malignancy it is of great importance to avoid handling the tumour unless it is free from adhesions, when, of course, it should be removed in the ordinary way. If, as is often the case, the growth is found to have infiltrated and formed adhesions to the neighbouring parts it is very undesirable to penetrate it with the finger—a thing which is very easy to do when the growth is soft, because it certainly seems to greatly increase the rapidity with which the disease subsequently spreads.

Ovariotomy has nowadays become such a common operation, and so much has been written about it, that it is not necessary for me to speak of it in any detail. The results of the operation have year by year shown a lessening mortality until at the present day it is quite exceptional for it to be followed by a fatal issue. Among my own series of fifty cases, which represents all the ovariotomies performed by me up to the present time, there has been no death, and in the great majority of the cases the convalescence was free from any exciting incident. The success which attends the operation is undoubtedly dependent on a rigid attention to all the details of antiseptic surgery. It is difficult enough to always attain to the ideal, and there will probably still occur from time to time an occasional death from septic infection,

TABLE SHOWING PARTICULARS OF FIFTY CASES OF OVARIOTOMY.

No.	Age.	Date of operation.	Place of operation.	Nature of tumour.	Result.	Remarks.
1	58, widow.	1892 Sept. 15th	Royal Hospital for Women and Children	Mainly solid; some cystic spaces, probably sarcomatous; right.	Recovered	Patient died two years later with recurrent growth in abdomen.
2	26, married.	Nov. 5th	Ditto	Papillomatous; right.	Ditto	Suffered from mitral stenosis.
3	42, married.	1893 Jan. 14th	Ditto	Papillomatous; left.	Ditto	—
4	25, married.	Jan. 20th	Ditto	Suppurating; right.	Ditto	Drainage; sinus formed; subsequent removal of silk ligature followed by closure of sinus.
5	26, married.	Jan. 27th	Ditto	Broad ligament cyst; left.	Ditto	Cyst dipped deeply into the pelvis; enucleation was difficult; cavity drained. A few days later fæcal matter came through tube; subsequently healed soundly.
6	50, married.	May 18th	Ditto	Papillomtaous; right.	Ditto	Very adherent to bowel and omentum.
7	33, married.	June 20th	Ditto	Multilocular; left.	Ditto	—
8	48, married.	June 27th	Ditto	Solid; soft and friable; probably malignant; left.	Ditto	No adhesions.
9	38, married.	Dec. 22nd	Ditto	Broad ligament cyst; right.	Ditto	Enucleation; drainage of cavity.
10	29, single.	1894 Feb. 6th	Ditto	Sarcoma; right.	Ditto	Large tumour; adherent to under surface of liver; small portion left behind. Left hospital three weeks after operation; subsequent death from recurrence.
11	36, single.	Feb. 20th	Ditto	Fibroma; right.	Ditto	Extensive attachment to back of broad ligament.
12	51, married.	March 13th	Ditto	Broad ligament cyst; right and left.	Ditto	Patient had a large uterine fibroid, which was left untouched. Cysts enucleated; cavity on right side drained.
13	32, married	July 3rd	Ditto	Papillomatous cyst; left.	Ditto	—
14	24, single.	Aug. 21st	St. Mary's Hospital	Multilocular; right.	Ditto	—
15	45, married.	Sept. 18th	Ditto	Multilocular; right.	Ditto	Twisted pedicle. Tumour contained blood.
16	38, married.	Oct. 9th	Royal Hospital for Women and Children	Multilocular; right.	Ditto	During convalescence had an attack of right lobar pneumonia lasting six days, ending by crisis.
17	29, married.	Oct. 23rd	Ditto	Parovarian; right.	Ditto	—
18	48, married.	Nov. 1st	Ditto	Multilocular.	Ditto	—
19	15½, single.	Dec. 5th	Ditto	Multilocular; right.	Ditto	Suffered from complete procidentia uteri.
20	37, married.	Dec. 14th	Ditto	Multilocular; right.	Ditto	Twisted pedicle very adherent.
21	43, married.	1895 Jan. 17th	Ditto	Unilocular; left.	Ditto	—
22	44, married.	Feb. 22nd	Ditto	Partly solid.	Ditto	Suffers from mitral stenosis.
23	44, married.	Feb. 25th	Ditto	Papillomatous; right.	Ditto	Patient operated on for similar tumour on left side, Jan. 14th, 1893 (see Case 3).
24	21, single.	April 23rd	Ditto	Multilocular; right.	Ditto	Tumour reached to ensiform cartilage.
25	32, married.	May 21st	Ditto	Multilocular; left.	Ditto	—
26	16, single.	June 25th	Paddington Infirmary	Multilocular; right and left.	Ditto	Operated on by request of Dr. Hillier; tumour on left side larger than that on right.
27	41, married.	July 4th	Royal Hospital for Women and Children	Bilateral; right suppurating.	Ditto	Vermiform appendix closely adherent to cyst on right side.
28	29, single.	Aug. 10th	St. Mary's Hospital	Dermoid; right.	Ditto	Procidentia uteri.
29	39, married.	Aug. 23rd	Royal Hospital for Women and Children	Multilocular; right.	Ditto	—
30	32, married.	Aug. 31st	St. Mary's Hospital	Papillomatous cyst; right.	Ditto	—
31	25, single.	Aug. 31st	Royal Hospital for Women and Children	Parovarian; right.	Ditto	—
32	56, married.	Sept. 10th	St. Mary's Hospital	Papillomatous; left.	Ditto	—
33	31, married.	Dec. 21st	Royal Hospital for Women and Children	Dermoid; right.	Ditto	Operation on fourth day of puerperium; tumour ruptured during labour and vagina was lacerated.
34	22, married.	1896 Jan. 7th	Ditto	Multilocular; right.	Ditto	—

TABLE SHOWING PARTICULARS OF FIFTY CASES OF OVARIOTOMY—*continued*.

No.	Age.	Date of operation.	Place of operation.	Nature of tumour.	Result.	Remarks.
35	31, single.	March 12th	Metropolitan Hospital	Parovarian; left.	Recovered	—
36	64, widow.	March 25th	St. Mary's Hospital	Multilocular; left.	Ditto	—
37	39, married.	April 13th	Royal Hospital for Women and Children	Parovarian; right.	Ditto	—
38	46, married.	June 2nd	Ditto	Bilateral; right suppurating, left dermoid.	Ditto	Much emaciated; tumour on right side, very adherent; drainage for twenty-four hours.
39	63, married.	June 8th	Nursing home	Multilocular; left.	Ditto	Patient suffered from diabetes mellitus; tumour had ruptured, and abdominal cavity contained much colloid material.
40	27, single.	June 29th	Royal Hospital for Women and Children	Multilocular; left.	Ditto	—
41	21, single.	July 14th	Ditto	Parovarian cyst; left.	Ditto	—
42	32, married.	Aug. 24th	St. Mary's Hospital	Papillomatous; left.	Ditto	Cyst was intra-ligamentous.
43	29, single.	Aug. 28th	Metropolitan Hospital	Dermoid; left.	Ditto	—
44	34, married.	Sept. 5th	St. Mary's Hospital	Suppurating cyst; right.	Ditto	Patient very thin and ill; tumour to navel: many adhesions.
45	27, single.	Sept. 8th	Ditto	Multilocular; right.	Ditto	—
46	36, married.	Sept. 29th	Ditto	Multilocular; left.	Ditto	Large amount of ascitic fluid.
47	39, married.	Oct. 27th	Royal Hospital for Women and Children	Broad ligament cyst; right.	Ditto	Tumour very adherent; right Fallopian tube inflamed.
48	56, married.	1897 Jan. 26th	Ditto	Multilocular; left.	Ditto	Twisted pedicle; universally adherent.
49	22, single.	Feb. 9th	Ditto	Parovarian; left.	Ditto	Tumour occupied the whole abdomen.
50	64, married.	Feb. 25th	Nursing home	Multilocular; right.	Ditto	Patient suffers from diabetes; tumour of left ovary removed June 8th, 1896 (see Case 39); tumour had ruptured and abdomen contained much glairy fluid.

but when such a death from such a cause does occur it is somebody's fault and indicates a flaw in the antiseptic precautions adopted. Shock is, perhaps, almost the only cause of death after abdominal operations that we cannot altogether eliminate. There is, however, nothing in the whole range of surgery so difficult as to be consistently clean. Instruments and ligatures are boiled and then transferred to a tray of carbolic lotion, from which the operator takes them as necessity arises, without the intervention of any assistant. Very little time is lost by this arrangement and the risk of infection arising from this source is minimised. The sponges are taken by the operator or his assistant from a bowl of carbolic lotion, and wrung out as required. The operations for the most part were performed in a small theatre which is used for general surgery of all sorts, and the patient was subsequently removed to the general ward.

All operators have their special fads, and personally I lay considerable stress upon a short abdominal incision and the ligature of the pedicle in three or more sections except when it is unusually narrow. A three-inch incision is generally quite long enough unless the abdominal wall is unusually fat or the adhesions are very numerous. Exposure of the intestines is thus avoided and the likelihood of the scar yielding is considerably lessened. By ligaturing the pedicle in more than two sections the chance of secondary hæmorrhage from slipping of ligature is practically eliminated. As to the value of irrigation of the peritoneum with boiled water or saline solution there is much difference of opinion. For my own part I very seldom employ it—only three times in fifty cases of ovariotomy, and in two of these cases it was had recourse to simply as the readiest method of removing large quantities of very tenacious ovarian fluid which had previously escaped into the abdominal cavity from rupture of the cyst. If the peritoneum be soiled by the escape of some of the contents of a suppurating cyst it can be cleansed quite as effectively by sponging as by irrigation, and in such cases it is not by any means always necessary to drain. I have had considerable experience in the operation for the removal of suppurating tubes and ovaries and have never had occasion to regret that irrigation was not employed. If the results obtained by one who does not irrigate the abdomen are as good as those obtained by one who does, then the claims of irrigation fall to the ground. The abdominal incision is closed by means of silkworm gut sutures and no iodoform is used. The application of iodoform is certainly of no use, though it probably does no harm. The wound is dressed for the first time on the eighth day and half the sutures are then removed, the remaining half being left *in situ* for another five or six days. Of the after-treatment of cases of ovariotomy there is but little to say. If the patient is infected at the time of the operation she will almost certainly die, and if she is not she will almost certainly recover. An aperient is given on the third day, and castor-oil is usually the drug administered because of its reliability, and when the bowels have acted the patient is allowed to have solid food. The amount of misapplied energy that has been expended on patients after ovariotomy is enormous and does not appreciably influence the recovery. It is the precautions that are taken during the operation and not those that are taken afterwards that determine the fate of the patient.

Weymouth-street, W.

WEST OF ENGLAND EYE INFIRMARY, EXETER.—The annual meeting of this institution was held on Oct. 29th under the presidency of Mr. G. Franklin, J.P. The treasurer's statement showed that the ordinary receipts amounted to £1257, as against £1272 last year, and the ordinary expenditure was £1317, as compared with £1239 of the preceding year. The medical report stated that there had been 2780 patients under treatment during the year, of whom 2412 had been discharged (being 603 cured and 1758 benefited), leaving 327 out-patients and 41 in-patients under treatment on Sept. 30th. The daily average number of in-patients had been 41. The chairman expressed regret at the continued inability of the committee to proceed with the new buildings owing to lack of funds, the building fund at present being only £433, and added that although everything had been done that could be done the present institution was seriously defective in many respects.

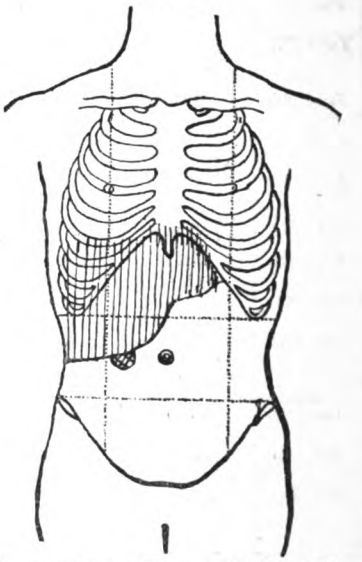
A CASE OF ANTEVERTED WANDERING LIVER.

BY RAYMOND CRAWFURD, M.A., M.D. OXON., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE ROYAL FREE HOSPITAL AND TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

IN his "Treatise on Diseases of the Liver" the late Dr. George Harley wrote: "There is yet another possible source of error, though from its extreme rarity an error is unlikely to be committed. But, as the mistake is said to have once occurred, and it is quite possible it may occur again, it is but right that I should call attention to it—namely, the possibility of mistaking an anteverted small liver for an enlarged one." In the case that I record below, history has repeated itself to my own discomfiture. I have appropriated the term "anteverted" rather than "moveable" liver because the condition was rather one of axial rotation than of excessive mobility of the organ. The case will be seen to be one of peculiar interest, both because of the symptom complex and its post-mortem corroboration, and of the histological condition of the liver.



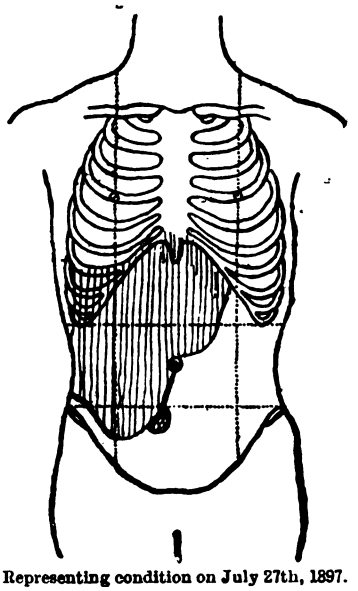
The patient, a woman, aged sixty-five years, attended the out-patient department of the Royal Free Hospital on May, 14th, 1897, and every subsequent week till July 7th, when she was admitted to the wards under my care. The following was the history of the patient when first seen. She complained of progressive weakness and pain all over, and there was yellowness and itching of the skin. The patient was married, but had had only one child, which was stillborn at full term; there was no history of parental tubercle or carcinoma; she had had twelve brothers and sisters, of whom only two were living, one brother having died from phthisis and the rest from unknown causes. When quite a child she had suffered with generalised dropsy; she did not know the cause of it but it was not associated with scarlet fever which she also had in childhood. The patient had had a left inguinal hernia for twenty-three years and hæmorrhoids for some years. Six months previously jaundice had set in insidiously with some abdominal pain but not of any severity. At the time she suffered a good deal from vomiting of a paroxysmal type, and was obliged to call in a medical practitioner, who ordered her to bed. In the course of a week or two the attacks of vomiting gradually subsided, but she lost flesh steadily. The jaundice became more intense; the appetite was completely lost; solids caused immediate nausea, so that only liquids were taken; since the illness commenced she had taken a quartern of gin daily, but prior to that she had never exceeded one and a half pints of ale a day. The bowels were at first constipated and the motions whitish and foul-smelling.

On May 12th she attended the out-patient department and was found to be in the following condition. There was intense obstructive jaundice of four months' duration. Liver dulness commenced at the sixth rib in the right mammary line and at the eighth rib in the mid-axillary line, and the edge could be felt at the level of the umbilicus. The enlargement appeared to be entirely of the right lobe; the surface was smooth; the edge was very hard and blunt; no nodules could be felt; and there was no pain on pressure. The gall-bladder could be clearly felt distended and projecting from beneath the edge of the liver about three inches to the right of the umbilicus.

Cancer of the liver was suspected, although no nodules could be felt and there was no marked tenderness or pain, but a primary seat could not be detected in the uterus or bowel, nor were there any indications of cancer of the stomach or head of the pancreas, so that the distended gall-bladder was fixed upon as the possible primary focus from which the disease had spread directly to the under-surface of the liver. The lungs were emphysematous and dry rhonchi were heard here and there on each side of the chest. For the next two months nothing special occurred beyond gradual emaciation and asthenia, with occasional attacks of acute pain in the right hypochondrium of a colicky nature. The constipation was relieved by a daily morning dose of mistura alba.

On admission to the wards on July 7th the patient was found to be much emaciated, and the conjunctivæ and the skin were a deep yellowish green in colour. The patient expressed herself as much more comfortable in bed than when getting about; she lay chiefly on her back, but could lie in any position. There were complete anorexia and frequent nausea; the mouth was very dry and there was a constantly unpleasant taste; the tongue was coated with a dry and dirty whitish fur; there was no pain and the patient rarely vomited after food. A good deal of troublesome flatulence was present; the bowels were now regular, but the motions were loose and white; the stomach was not distended, and no tumour could be felt there. The superficial abdominal veins on each side were enlarged; there was obvious fulness of the right hypochondriac and lumbar regions, extending into the epigastrium, but the abdomen as a whole was

FIG. 1.



Representing condition on May 12th, 1897.

swagged over to the left, the intestines being apparently pushed *en masse* to this side; there was a large left inguinal hernia. The abdominal walls were very thin and flaccid, and the recti were separated; there was some tenderness on the right side of the epigastrium; a considerable tumour was felt reaching as low as the right iliac region, and entending upwards beneath the ribs. The percussion note was dull from the seventh rib in the mammary line to the lower edge of the tumour, which was felt to be the right lobe of the liver; its features have been already described. The gall-bladder could be felt clearly midway between the pubes and the umbilicus; a little to the right of the median line; the point of the finger could be readily inserted between the gall-bladder and the edge of the liver. The spleen could not be felt and was not enlarged to percussion. There was slight œdema of both legs, and there were some purpuric spots on the shins. The catamenia had ceased at the age of fifty-two years; for three months there had been a yellowish, quite odourless, discharge from the vagina. On examination per vaginam the cervix uteri was found to be atrophied; no induration was present; the fundus could not be felt, and the fornices were free. Per rectum no tumour was felt, but external hæmorrhoids were present. The urine was deep greenish in colour, of specific gravity 1008, and faintly acid; it contained no albumin, sugar, or blood, but bile pigment was abundant. The arteries were slightly thickened; the heart's impulse was feeble, but it was felt in the fifth interspace, just internal to the nipple; and the cardiac area and heart sounds were normal. The pulse was 80. The patient had had a cough for many years on and off; it was especially troublesome in the morning; the expectoration was yellowish and frothy. She was short of breath and her voice was hoarse and weak; the chest wall was much wasted, deeply jaundiced, and moved but little in respiration, though the movements were equal on each side. Behind, the lower ribs on the right side were much more prominent than those on the left; vocal fremitus was normal; there were a few palpable rhonchi. There was general resonance on percussion; the breath sounds were rather harsher over the right side than the left; expiry was

Digitized by Google

prolonged all over; there were generalised rhonchi, and the respirations were 16. On July 13th there was a good deal of dragging pain in the lower part of the back and also over the epigastrium and left hypochondriac region, which made the patient feel very faint. On the 16th there was similar pain confined to the right side of the abdomen. On the 20th, for the first time, the left lobe of the liver could be felt distinctly increased in size; the right lobe was steadily descending; the gall-bladder seemed more solid and fluctuation was not now so readily obtained; the abdomen measured 31½ in. at the level of the navel. On the 27th it was noted that during the previous three days the liver had distinctly descended as much as two or three inches, and the right lobe was then only an inch above the middle of Poupart's ligament; the whole edge of both lobes could be plainly felt, and there was a small amount of moveable fluid in the flanks. The intestines were thrust still further over to the left side; the liver was painful on pressure; so was the gall-bladder; the edge could not be pushed up, and the abdomen was 30¾ in. at the umbilicus.

FIG. 2.

Representing condition on July 27th, 1897.

On the 30th there was no more pain, but the irritation of the skin was renewed; rhonchi were present all over the chest behind. The entry of air was not so free at the left base as at the right. The bowels opened regularly. The urine showed a trace of albumin but no casts, and the ascites was increasing. By Aug. 5th the patient had become more and more feeble and emaciated. There were several purpuric spots on the legs; the temperature had undergone slight remissions for two or three days. Until the 16th there was steady progress of the weakness and emaciation; the patient complained of drowsiness and chilliness, but there was no pain. The abdomen then measured 32½ in. at the umbilicus; there was no further enlargement of the liver and no tenderness; the jaundice was deeper. By the 19th diarrhœa had set in and more bronchitis; the patient was given a starch and opium enema, which diminished the diarrhœa, and also some carbonate of ammonia and tincture of squills. By Sept. 3rd no material change had been noted, but there was a steady decline of strength; there was more diarrhœa; the whole abdomen was very tender, and the patient could not bear the lightest touch. On the 10th there was an increase in the diarrhœa; the abdomen was more distended; much bronchitis was present, and the patient was gradually sinking. Death took place on Sept. 11th.

Necropsy.—A post-mortem examination was made eight hours after death. The body was much wasted, the abdomen was distended, the skin and mucous membranes were deeply pigmented. On opening the thorax the left pleural cavity was found to be obliterated behind by old adhesions; a small quantity of serous fluid was discovered in the right pleura; the right lung contained a caseous nodule at the apex, but otherwise it was normal, and the bronchial secretion was bile-stained. In the heart the muscle was pale, flabby, and bile-stained, but the cavities and valves were normal. The abdomen was full of bile-stained serum, the intestines were driven over to the left side, the liver was completely anteverted and lying on the intestines in the long axis of the abdomen, the lower edge of the right lobe was not much more than a hand's breadth below the costal margin in the right mammary line, and the liver surface was smooth, and its consistence firm, especially at the edges. The weight of the organ was 54 oz. and its transverse measurement was 10 in. On section the liver was dripping with bile and deeply bile-stained, and the bile ducts within the liver were distended to the size of the little finger and full of thick, green bile. The liver was not specially mobile apart from the other viscera; there was no mesohepar and no apparent elongation of the ligaments. The gall-bladder was hypertrophied and much distended with deep-green bile, some of which was semi-solid, and its peritoneal sheath was thick and opaque. The cystic duct was distended, the hepatic duct was markedly so, and the common duct was not distended; the walls of the duct were normal; bile papilla was patent. The bile could be expressed readily from the gall-bladder into the intestine and a good-sized catheter could be passed throughout the ducts. There were no glands in the portal fissure or stones or adhesive bands. The spleen was slightly enlarged and firm, and adherent to the parietes by partially organised adhesions; there had been recent perisplenitis also. The stomach was not dilated. The pancreas was normal. Neither kidney was moveable.

Microscopical examination of the liver showed extensive dilatation of the bile ducts, and around these widespreading pericholangeal fibrosis. The greater part of the liver was markedly œdematous—a condition that could also be seen in the cirrhotic areas around the bile ducts. The atrophy of the liver cells was fairly uniform throughout the liver and not specially marked close around the distended bile-ducts. Here and there could be seen a suspicion of unicellular cirrhosis, but only in a few small and isolated areas; there were no pseudo-bile canaliculi and no intra-hepatic calculi could be seen. For the microscopical sections, all of which were admirably cut and stained, I am indebted to Miss Webb, M.B. Lond., curatrix of the museum of the Royal Free Hospital.

Remarks.—In searching through the literature of hepatoptosis I find two cases only in which the signs were almost identical with those in the above case but in each of these there was a great difference in the symptoms. The one is recorded by Peters,[1] in which the liver was found resting on its under surface with its long diameter parallel to the median line of the body, the right lobe being lowest and on a level with the anterior superior spinous process; and the other by Griffiths,[2] in which, in a man, aged fifty-four years, "the liver dulness extended from two fingers' breadth below the nipple to the crest of the ileum and partly into the iliac fossa, eight inches in the perpendicular right nipple line." Yet at the necropsy the organ was found to measure only ten inches transversely and eight inches in the antero-posterior direction, weighing fifty-six ounces. This unusual state of affairs, he says, was due to "the liver lying on its under surface in the lumbar region, the anterior edge of the right lobe being down in the iliac fossa. The organ appeared as if it had been partly rotated upon its own transverse axis—or, in other words, anteverted—so as to allow its upper surface to be felt through the abdominal wall below the ribs."

This was precisely the condition in life in the above case, the liver at first being anteverted and also rotated from right to left so as to bring the right lobe below. In this way the vertical upper limit of liver dulness remained unchanged until the liver descended *en masse*, and it was possible then to feel the edge of the left lobe of the liver. The post-mortem findings suggest that the jaundice that persisted from the very outset must have been due to kinking or torsion of the bile duct—indeed, bearing in mind the limits of distension of the ducts outside the liver, the evidence is almost demonstrative, the site of the kink being at the commencement of the common duct. In the absence of any severe attack of colic the constricting process would presumably have been a slow one. With the final descent of the liver on came ascites, which may reasonably be

[1] New York Medical Gazette, 1882, p. 412.
[2] Harley: Treatise on Diseases of the Liver, p. 54.

Digitized by Google

referred to kinking of the portal vein. The œdema of the legs may similarly have been due to a partial occlusion of the inferior vena cava from traction Another point of interest is the position of the liver after death, in no way corresponding to the ante-mortem demarcation. The same circumstances led Wickham Legg[3] to disbelieve the existence of true hepatoptosis, except in mistaken diagnosis. Packard,[4] however, records a case in which before death the liver edge reached from nine to ten centimetres below the costal margin and post mortem it was in its normal position under the diaphragm and almost hidden by the costal cartilages. Landau[5] likewise points out that the diagnosis of hepatoptosis has not been conclusively established by necropsy. Yet the condition is only to be expected with the ascent of the diaphragm that occurs at death; and the reality of hepatoptosis has been confirmed both by abdominal section and post-mortem observation. It is difficult to say whether the descent of the liver was, as Glenard holds, merely a terminal incident of a general enteroptosis. No such condition was discerned either before or after death, but the readiness with which the intestines wandered into the left flank, and the existence of an inguinal hernia on the left side suggest such a possibility; also the liver, though so extensively displaced, was very slightly mobile apart from the intestines. On the other hand the stomach was normally situated and there was no associated mobility of the kidneys. Glenard mentions albuminuria and leucorrhea as conditions associated with hepatoptosis, and both were present in this case, but the albuminuria may well have been a secondary effect of the jaundice, and though leucorrhea may be a sequel of enteroptosis it can hardly be a direct sequel of hepatoptosis.

In any given case it is difficult to assign the exact causation to a moveable liver: in this case the abdominal walls were remarkably pendulous. Landau regards this as the main cause of hepatoptosis, and Graham[6] found a distinct relation to frequent pregnancy at short intervals, nearly all cases of non-traumatic origin occurring in women. The intestines act as a cushion which supports the liver in its position under the diaphragm by the even pressure of healthy abdominal muscles. But obviously flaccid abdominal walls do not alone produce hepatoptosis, as the former condition is very common, the latter very rare. Graham showed in the cadaver that, in the ordinary way, the ligaments were strong enough to carry the whole weight of the liver without the abdominal walls: simple opening of the abdomen seldom induced any descent of the liver. He also found that after opening the abdomen and cutting the suspensory ligament the anterior border of the liver descended about three inches, the right lobe more than the left, while the posterior margin remained fixed. This would necessarily produce anteversion such as occurred in the present case; yet post mortem we were unable to make out any elongation of the suspensory ligament, such as might result from increased traction by loss of the support of the abdominal walls. Winkler[7] supports the theory of elongation of the suspensory ligament, and Wassilief[8] has actually seen such a condition. It must be borne in mind, however, that there is no proof that this ligament is normally tense in the healthy subject. In my case there was no mesohepar, which, according to Hirtz, exists only in Meissner's imagination, and the other ligaments appeared perfectly normal. Faure[9] is disposed to regard the coronary ligaments and the connective tissue investment of the inferior vena cava as the true suspensory ligament of the liver; this would harmonise with the clinical condition of our case, the general descent being due to weakness of the coronary and lateral ligaments, the right lobe by reason of its greater weight descending first and most. Faure attributes the lengthening of the ligaments to a general nutritive defect leading to stretching of the fibrous tissues generally, and so causing both flaccidity of the abdominal walls and weakness of the ligaments. Descent of the liver has been laid to the charge of tight lacing, but this phantom tends to crop up whenever a disorder is specially incident on the female sex. Whatever may have been her habits in the green tree, there was no indication of such a cause in the sere and yellow leaf; moreover, as Graham remarks, tight lacing leads to errors of form rather than of position of the liver.

In most of the recorded cases, as in this, the onset of the symptoms has been insidious; sudden onset is usually, but not always, traumatic, and is marked by the familiar symptoms of severe biliary colic. There has usually been dull aching pain, worse on exertion; my patient referred her most constant pain to the lower part of the back and between the shoulders, and described it as dragging. Pain and tenderness over the liver only became a prominent feature in the late stages, when the œdema present must have exerted a great distending force on the liver. The intense general abdominal pain of the later stages was probably referable to the recent peritonitis, which was found over the spleen. The dragging pain was always worse on exertion, but not completely relieved by recumbency.

The histological characters of the liver are peculiarly definite. The most striking feature is the widespread atrophy of the liver cells; apparently this is not a purely mechanical process, as the atrophy is equally marked away from the distended bile-ducts as in their immediate environment. No doubt the degree of œdema manifested under the microscope would have greatly generalised the pressure, but much of the atrophy is probably due to icteric necrosis. It is surprising that so extensive a cellular atrophy should not have led to some degree of secondary connective tissue overgrowth, but such is conspicuously absent, only the most delicate capillary network being visible between the residual liver cells. Such a condition would suggest a somewhat rapid atrophy of the true liver cells. The limitation of the increased fibrosis to the bile-ducts is in this case indisputable. Respecting the œdema it must be borne in mind that not only was the *vis a tergo* diminished by the assumed constriction of the portal vein, but likewise a block may have existed ahead from traction on the hepatic vein or the inferior vena cava. It is true that much of the lymph drainage of the substance of the liver passes out at the portal fissure, and may have been involved in the local torsion, but obviously there must have been other channels of efflux patent or jaundice could not have occurred. Weber[10] surmises that the fibrosis about the bile ducts is due to organisation of scavenger cells that have been attracted to the part by the necrosed liver cells. This can hardly apply to the present case, as the atrophy is uniform and universal, while the fibrosis is strictly localised to the bile-ducts. Weber quotes some experiments of Nasse to show that the effect of ligature of the hepatic duct is to cause atrophy of the liver cells, and that if the obstruction be removed the liver cells are capable of undergoing some degree of regeneration. Of the former proposition there can be no doubt, but in the present case the persistence of the obstruction precluded a confirmation of the latter.

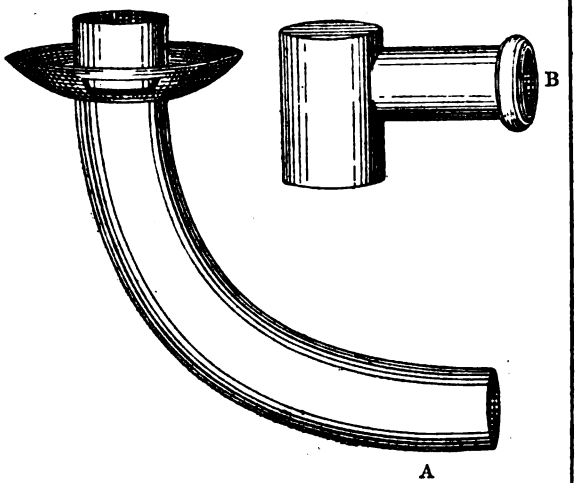
ADMINISTRATION OF ANÆSTHETICS THROUGH A TRACHEAL WOUND.

BY THOMAS ANNANDALE, M.D., F.R.C.S., F.R.S.EDIN.,
REGIUS PROFESSOR OF CLINICAL SURGERY, EDINBURGH UNIVERSITY.



IN March, 1887, I published in the *Edinburgh Medical Journal* a short paper upon Preliminary Tracheotomy as an Aid to Certain Operations. In this communication I described and figured a simple appliance for keeping a patient under the influence of chloroform or ether in connexion with operations which necessitated a previous tracheotomy. Since then I have used this appliance from time to time with success, but having found that the india-rubber tube connected to the tracheotomy tube was sometimes apt to get twisted at its point of connexion and so interfere with respiration, and also that matters coughed up were not readily expelled through the long tube, I have had my apparatus improved so as to lessen these risks. This modified appliance was recently employed with perfect success in a case of excision of the entire larynx and portion of the trachea together with a large and vascular thyroid tumour, the patient being now quite convalescent.

This improved apparatus is as follows:—1. An ordinary full-sized silver tracheotomy tube having its upper end extended

Digitized by Google

for about half an inch beyond the shield (see Fig. 1, A); 2. A silver cap (Fig. 1, B), having a short tube of the same metal projecting at right angles from it and to which one end of an indiarubber tube is connected. In Fig. 2 is shown the cap fitted on to the tracheotomy tube. The cap fits easily and can be at once lifted off the tracheotomy tube and also turned round so as to allow the attached indiarubber tube

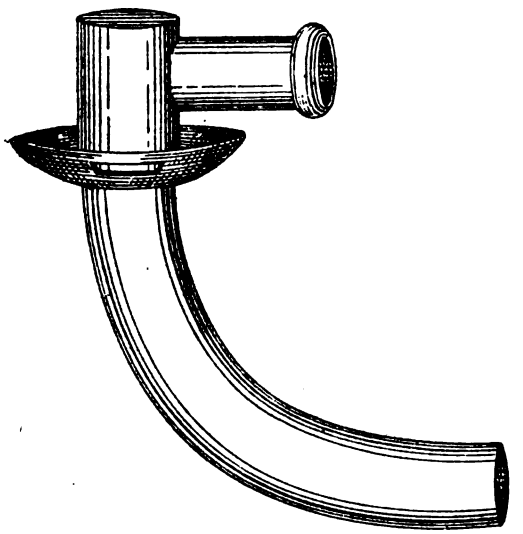


FIG. 1.

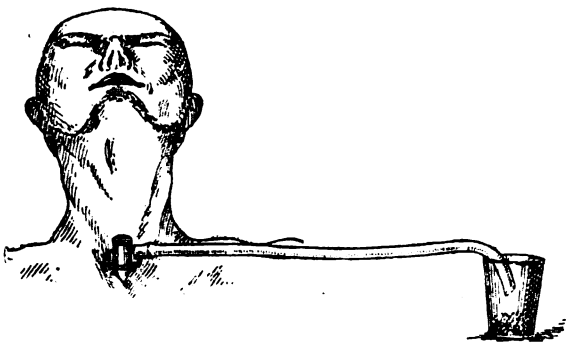
Tube with cap disconnected.

to project on either side which ever may be found most convenient for the administration of the anæsthetic. 3. A portion of indiarubber tubing. The length of this should be about two feet, but it may be used shorter or even a little longer, and the diameter I prefer is about half-an-inch. 4. An ordinary glass tumbler or other similar receptacle with a small piece of lint or absorbent wool placed at the

FIG. 2.



Tube with cap in position.

bottom upon which the chloroform or ether is from time to time sprinkled. In Fig. 3 the whole apparatus is shown in position.

The anæsthetic—I prefer chloroform—may in the first instance be held over the tracheotomy tube with the cap off, and when the time for the operation has come the cap with attached indiarubber tube is put on and the anæsthetic inhaled from the tumbler, the anæsthetist standing or, if he prefers, sitting well away from the operating table, holding the tumbler in one hand and with the other steadying the tube. To prevent blood or vomited matters passing into the air-passages during the operation the introduction of a piece of sponge or other plug into the trachea above the tracheotomy wound is usually satisfactory but in the case of the excision of the entire larynx already referred to I adopted a thoroughly effective and as far as I know original method and I am inclined to think that this plan may be used in other cases. The procedure was to pass round the trachea immediately above the tracheotomy wound an indiarubber cord and by means of it to ligature the canal temporarily so as completely to prevent the entrance of any fluids or other matters into the air-passages. When the ligature was removed at the completion of the operation above referred to the walls of the trachea did not appear to have been injured by it. It is true that the condition of the tracheal rings in some instances might prevent such a ligature being perfectly

FIG. 3.

Cap connected with indiarubber tube dipping into vessel containing wool and anæsthetic.

effectual, but I am of opinion that this means of temporarily closing the trachea is worthy of consideration and trial.

The advantages, then, claimed for the appliance which I have figured are: 1. It is simple and at the same time effectual. 2. The cap being moveable can if necessary be at once disconnected from the tracheotomy tube, so as to allow mucus or other matters to be more easily expelled from the air passages. This mobility also allows the cap and connected indiarubber tube to be turned round to either side. 3. It allows the anæsthetic to be administered at some distance from the patient, and so does not interfere with the operative procedure. 4 The anæsthetic when inhaled through the long tube is not likely to be so irritating to the air passages as when it is more directly inhaled through the tracheotomy tube itself.

Edinburgh.

CHRONIC MENINGITIS AS A SEQUELA OF EPIDEMIC CEREBRO-SPINAL MENINGITIS.

BY EDMUND HOBHOUSE, M.D. OXON., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL, BRIGHTON.

THE following case is probably an example of what Sir William Gowers has described as chronic internal pachymeningitis due to the epidemic disease; it is not described, so far as I can discover, as an ordinary sequela, and must certainly, I think, be rare in such a well-marked form, closely resembling the form of pachymeningitis due to caries and suppuration.

The patient, a man aged twenty-one years, always healthy but for this trouble and with a good family history, had an attack of cerebro-spinal meningitis during a severe epidemic at the Cape in 1877.[1] He had one relapse within three weeks, but otherwise recovered well, though there was a distinct history of impaired vision during convalescence, from which he gradually recovered. After that he was in good health up to fifteen years of age and led an outdoor life, joining in athletics and playing football. At about the age of fifteen years he began to notice pain in the left hip which at first only came by day and after exertion, but latterly was most severe at night. For two years this

[1] Hirsch (Geographical Pathology, vol. iii) asserts that there have been no outbreaks in the southern hemisphere, but I believe there is sufficient evidence as to the occurrence of this one.

Digitized by Google

continued to get worse and he took to his bed. The right leg became affected and the muscles of the thighs began to waste. In August, 1887, when nineteen years old, he had measles, and after this what was called intermittent fever for two months. The temperature ran up to 104° F., at times with vomiting and severe pain. The legs became very rigid and the calves began to waste; he was treated by dry-cupping, wet-cupping, and postural extension of the nerves, and owing to the pain was kept under morphia almost continuously from August to January. At one time during this period he had severe pain in the occiput with, he believes, some retraction; pressure on the spot sent the pain down the back. He had some difficulty with both bladder and rectum, and also had priapism. For about a year he had to have enemata. He never had any affection of the arms. He improved after this—in 1888—but had one severe relapse from catching cold. When admitted into St. Thomas's Home, in May, 1890, the legs were very wasted and he could just walk 20 yards with crutches. There was no sign of any vertebral disease, and except for the wasting of the legs, which affected all the muscles evenly, the patient was well nourished. The arms were unaffected. The muscles reacted feebly to both currents and with slight reaction of degeneration. The knee reflexes were exaggerated; the plantar reflexes were brisk, especially the left; and there was no ankle clonus. The legs were very rigid and could only be flexed with great difficulty and pain. There were fairly frequent attacks of severe pains radiating all down the legs. Sensation was not much affected. There was constipation, but no very definite affection of the sphincters. The eyes, which Mr. Lawford kindly examined, showed distinct traces of previous optic neuritis, with narrowing of the vessels and slight pallor. Vision was not seriously impaired, though he had noticed increased defect after his illness in 1887. There was no defect in the movement of the eyes. There was no other paralysis. Massage and the constant current produced no effect apparently, but he began to improve after taking strychnia. Gradually the pains left him, and by January, 1890, he had been walking for four months and was fairly free from pain for three months. The nutrition of the muscles had improved immensely. He still had pains, which were referred to the sciatic nerves, and were worse after exercise; he also had occasional pains in the eyes and head. Subsequently he recovered sufficiently to return to the Cape and resume his life there, and he reported himself in good health six months later.

Remarks.—This case shows how long the effects of cerebro-spinal meningitis may last; it is clear, I think, that the whole trouble dates from the attack as a child, for the pains never really left him though limited to the legs. Probably the special incidence on the lumbar region was due to the gravitation of the inflammatory products to the lower part of the cord, leaving a permanent thickening of the membranes. The entire escape of the arms is interesting, though not very unusual; *a priori* one would have expected that some lodgement of the inflammatory process might have occurred at the cervical enlargement.

It is a question whether the so-called measles in 1887 may not have been a recrudescence of the original disease, as rashes of different kinds are common in its course; but, on the other hand, serious meningeal affections are not very rare after measles and would be specially liable to occur where the meninges were already much damaged. In any case the almost complete recovery after twice-repeated inflammatory attacks, extending apparently from the optic tract to the cauda equina, is noteworthy.

I must express my thanks to Dr. Edmunds for his kindness in allowing me to publish this case, which only came under my care during his short absence.

Brighton.

VACCINATION WITH CALF LYMPH.—At a meeting of the Redruth Board of Guardians, held on Oct. 29th, a communication was read from the Local Government Board recommending that sixpence per case extra for vaccinations performed with calf lymph would be a sufficient remuneration for the medical officers. The Board added that the guardians themselves could not supply calf lymph except in the case of an outbreak of small-pox. It was eventually resolved that sixpence be allowed in each case where calf lymph was used, although one guardian moved that only threepence should be given.

PROFESSOR EDINGER'S THEORY OF THE CAUSATION OF SOME NERVE DISEASES.

BY R. CUNYNGHAM BROWN, M.B., B.S. DURH.

INTERESTING papers on the changes in the spinal cord in pernicious anæmia [1] and in profound anæmia [2] from the pens of Professor J. Michell Clarke, Dr. Taylor, and Dr. Semple, in which the morbid conditions are ascribed: (1) probably to some toxic condition of the blood, and (2) to a tendency to hæmorrhage, justify one—if justification be necessary—in laying before the readers of THE LANCET a short *résumé* of Professor Edinger's beautiful "Theory of the Causation of Some Nerve Diseases, in particular Tabes and Neuritis." [3] In particular, also, a letter by Mr Percy Furnivall [4] on certain affections of the nervous system illustrates and is at the same time elucidated by this theory.

Professor Edinger first discusses the surprising variety in the causes of nerve disease; the fact that any of these diseases may produce at one time one and at another a quite different disease; the difficulty in explaining how so many diseases are progressive, and continue to develop long after the primary injury has passed away; the column degenerations which result in animals after long-continued rotation on a turn-table; the degenerations which accompany pernicious anæmia and Addison's disease; and the question why in Friedreich's disease the posterior and lateral columns gradually degenerate, and why to these are so often added bulbar and other symptoms. To these and many other questions it has been impossible hitherto to give a satisfactory answer, and it is to their adequate explanation that this theory is directed.

The tissues of the body, the separate molecules indeed, which together form the cells, exist together in a condition of equilibrium. When one part becomes damaged it becomes weaker, loses its vitality, and becomes pressed upon and overgrown by its sounder neighbours. That such conditions of disturbed equilibrium obtain continually and in all parts of the body is undoubted. This fact, established first by C. Weigert, [5] and quite independently of him by W. Roux, [6] has been shortly described by the latter as "the struggle of parts of the organism." From Roux's important work we note (1) that this struggle of parts around a cell commences when in that cell the metabolic substance is more quickly consumed than restored; and (2) that Roux believed that the absence of impulses—the term impulses being used merely to designate, not to explain, certain processes—debilitated certain cell substances, and particularly in their power of assimilation. During development this struggle of cells and structures plays no small part. General pathology offers many examples. Weigert has already shown how in interstitial nephritis, in myocarditis, and also in the so-called grey atrophy of the central nervous system, the ground tissues in the first instance degenerate, and then the weakened tissues, pressed upon, overgrown by the connective tissue.—in the last-mentioned case by the neuroglia—become destroyed. As one of the most important phenomena of the struggle Roux specified the influence of entering impulses. Now Weigert has shown that the conception of "impulses" is in no way essential and that the simpler idea of physical pressure is more correct. According to Weigert neither the cell nor the organ are strengthened by impulses.

All diseases which attack the nervous system cause damage only through their influence on nerve cells or their processes. These injuries, whether transitory or permanent, never attack the cells alone or the fibres alone. The neuron, the compound of cell axis cylinder, and terminal branching, is one coherent entity. The degeneration of the fibre which follows destruction of its cell of origin has long been recognised. The

changes which take place in the fibre as the result, not of destruction, but merely slight injury to the cell, are on account of the inadequacy of our methods less known. Forel, however, first called attention to the fact that the cell itself suffers when separated from its fibre, even to complete atrophy if the division fell close to the cells. Hirsh found changes in the cells of the facial nucleus twenty-four hours after division of the peripheral facial nerve. These, however, are relatively coarse conditions in which the cells or fibres had been seriously damaged. Now during the activity of the nervous system certain bodies become used up which must again be restored. The methods which will be able to demonstrate the purely morphological changes which take place during the activity of a cell are as yet only in the initial stages; but it is known, through the investigations of Daschkiewicz Hodge, and Hirsh, that active cells look essentially different from those which have rested and also that the fibre participates in the change. If the anabolism equals the katabolism the cell will continue to live and perform its functions, but if not the weakened cell, overweighted by its sounder neighbours, will die. If, therefore, such conditions exist as an abnormally great performance of function with merely normal restorative potentiality, or normal function with abnormally low restorative potentiality, one should expect to find signs of degeneration equivalent to those met with as the result of gross mechanical disturbances.

That prolonged, forced exertion in any separate muscle-group can lead to its paralysis, and that the paralysis is atrophic, has long been known. These have always been regarded as cases of muscle atrophy as the result of neuritis. The hammer palsy of young smiths, the paralysis of muscles of the hand in cigar rollers (Cöster), the paralysis of separate extensors of the forearm in young drummers (Nürnberger Bruns) in fact, all the manifold "occupation-paralyses" furnish examples of nerve failure through exhaustion. This nerve failure may happen even in the healthy as the result of extreme over-function, but the majority of cases observed show symptoms of malnutrition. Paralysis in the muscles supplied by the radial nerve has been observed after prolonged crochet-work in an anæmic woman, extensor paralysis in a half-starved cane-plaiter, and many others too numerous to mention. One can understand, therefore, how Oppenheim, Siemerline, and Cöster found in the peripheral nerves of all people who had died from exhausting diseases and in those of very old people degenerated fibres. Now, no single nerve element can degenerate without others becoming indirectly affected. To take an instance from neuro-pathology, consider for a moment atrophy of the facial nucleus. The resulting paralysis of the facial muscles will gradually affect the bony tissues of the skull, and deformities and inequalities are brought about which later will react on the configuration of the brain. The flow of blood and lymph through the affected parts will be altered, and so changes will be initiated which must later be equalised by alteration in other structures. In the cases of "occupation paralysis" this co-relation of parts must take effect, and we should expect some participation of the sensory paths. Ernest Remak reports on many cases of pain and sensory disturbances in these cases.

The participation of the sensory paths will naturally vary with the intensity of the process and the extent to which sensory fibres are mixed with the motor. This condition of deficient restoration causes not only degeneration in the peripheral nerves, but also in the central nervous system. In anæmia, pernicious anæmia, after many fevers, and during many exhausting conditions, changes are observed in the spinal cord. By the term "grey degeneration" one recognises pathological forms originating in the degeneration of nerve elements, and the growth into their place of the interstitial tissue. Examination of the region of the entering posterior roots in cases of fresh tabes shows that long before the proliferation of the interstitial tissue takes place the wasting of the medulla and the degeneration of the axis cylinder have occurred. The degenerated parts, in the cases of pernicious anæmia, anæmia, ergotin poisoning, &c., are found most often in the posterior columns, much less frequently in the pyramidal or cerebellar tracts. Now it is generally accepted that these changes depend on the action of some toxic substance, and it is by no means asserted here that such toxic action may not exist, but it does not explain why in most cases the posterior columns are principally affected, nor why only some of those suffering from pernicious anæmia, &c., become affected in this way and others escape. To explain these matters according to the toxic theory a supplementary hypothesis must be added of "susceptibility of parts." Now it is *a priori* inevitable, according to Professor Edinger's theory, that those parts should first degenerate which suffer the heaviest demands upon their function.

Take tabes as an example. If one leaves out of count those automatic centres, isolated ganglion groups, which stimulate movement and take up sensation and which come into use mainly for the intestine, one finds that there are nerve-structures whose function is continually, or, at any rate, much more frequently, in demand than that of others—those, namely, which coördinate muscle sensation and which are necessary for the maintenance of the equilibrium of the body. The almost perpetual demands upon this apparatus, and particularly from the legs and trunk, are at once apparent. Now, according to this theory, this tract should be among the first to suffer, and disturbance of equilibrium, ataxy should be one of the first symptoms. And that this is so is known by everyone. But the theory also demands that this ataxy should be of more frequent occurrence in the active than in those who lead a sedentary life. This also is borne out by facts. Statistics prove the relatively greater frequency of tabes in men than in women. The proportion in Prussia and Russia is about eight to one. The fact that tabetic symptoms begin almost regularly in the legs and much later affect the arms is only one consequence of the continuous coördination required in progression and the maintenance of equilibrium as contrasted with the intermittent use of the arms. The form called "higher tabes" will probably be found to depend on the occupation of the individual. The greater demands upon those sensory nerves which serve the muscle apparatus than upon nerves of pure sensation explains the relative infrequency of sensory troubles in tabes. The almost constant sensory stimulation of the sole of the foot and the frequent irritation of the skin by the clothes explain the anæsthesia of the sole and the patchy anæsthesia of the skin found in tabes. These patches also preponderate in places where the skin would be subject to more frequent stimulation. But mechanisms which perhaps more than any of those mentioned suffer continued demands are those associated with the light reflex and accommodation. The first-named, that of the light reflex, is during waking moments continually in action, and its early disappearance is what the theory would lead us to expect. A beautiful illustration of this was afforded by a tabetic patient under the care of Professor Edinger, in whom the light reflex was absent only on one side. The patient was a watchmaker, and had used this eye incessantly at his work. The accommodation is, as one would expect, affected if at all much later. The order in which the external muscles of the eye are affected is also explicable by the theory. The occurrence of optic atrophy, bladder trouble, lingual and laryngeal paralyses, the affection of the peroneal muscles (*pied bot tabétique* of Charcot) and many other points in the symptomatology of tabes, all admit of a satisfactory explanation by the theory, but space does not permit of their discussion here. In particular, however, these frequently occurring anomalous cases of tabes, where for a long time, or even through a whole life, only one symptom of tabes is present, are elucidated. The progressive ophthalmoplegia of Westphal also and the various transitionary and compound forms of nerve disease are explained by and illustrate this theory which, though it leaves many questions still unanswered, elucidates many points hitherto obscure.

The application of the theory to Professor Michell Clarke's cases is manifest. The column degeneration as the result of the performance of function in people suffering from malnutrition has already been sufficiently discussed, and the hæmorrhages are explainable by Roux's corollary on "the co-relation of parts," from which under certain conditions vessel changes were to be expected. In this connexion a significant fact is noted in Case 2: "No hæmorrhages were noticed in the other organs post-mortem." This itself would seem to indicate that the hæmorrhages were secondary to changes in the nerve structures of the spinal cord itself. In the two cases mentioned by Mr. Furnivall it is to be noticed, firstly, that in his own case extreme demands upon a normal restorative power produced anæsthesia of the feet and in other cases ataxic gait, which passed off after rest; and secondly, that in the case of Mr. Furnivall, senior, with in all probability a diminished power of restoration, the sensory and motor disturbances ensued upon slighter exertion and passed off much less quickly.

It is to be regretted that in a paper of this length only

Digitized by Google

scant justice can be done to Professor Edinger's theory, but it may be hoped that this brief account will show that the theory deserves serious consideration.

Holmfirth, Yorks.

A CASE OF TEDIOUS LABOUR FOLLOWED BY DOUBLE PHLEGMASIA ALBA DOLENS AND GANGRENE.

By FRANK M. WILLCOX, M.B., C.M. EDIN.

THE patient was a primipara and thirty-four years of age, sparely built, weakly, and very anæmic, with feeble circulation, but no organic cardiac change. She suffered intensely with cold feet and hands and was treated during pregnancy for anæmia. The labour was very tedious, lasting forty-eight hours after she was first seen. On abdominal examination occipito-posterior presentation was diagnosed. On vaginal examination the os was found to be about the size of a two-shilling piece, and it dilated very slowly. The labour produced considerable exhaustion and was ultimately finished instrumentally; unfortunately, owing to the rigidity of the parts, the perineum was torn, but it was at once sutured and no blood was lost. After labour the pulse was 84, weak and thready, but regular, and the temperature was slightly subnormal. Stimulants were given and external warmth was applied. During the first fortnight of the puerperium the patient did well; the perineal tear healed, the temperature was never above 99·8° F., and she rose on the twelfth day. On the evening of the sixteenth day she was seized with violent pains in the left leg, and on seeing her next morning it was evident that phlegmasia alba dolens had set in. The leg was swollen, shiny, and white, the superficial veins were much distended, and in Scarpa's triangle and the popliteal space the limb was very tender to the touch. Unfortunately during the night an unskilled nurse had freely rubbed the leg to relieve the pain. There was no rise in temperature or abdominal tenderness, neither was there any evidence of uterine or vaginal sepsis. The usual treatment was adopted The patient was kept absolutely at rest, the foot of the bed was elevated, anodyne applications were used, the limb was enveloped in cotton wool, and external warmth was applied. The child was weaned; cardiac tonics and light nutritious diet were ordered. During the next few days the patient was easier, but complained of pain in her heel and toes. On the twentieth day discolouration was observed over the region of the great and second toes; this gradually deepened and extended, involving the foot as high as the transverse tarsal joint. The patient was fairly comfortable, however, till the evening of the twenty-third day, when there was an acute exacerbation; she was very restless, and the temperature rose to 100·6°. On the following morning the great and second toes and part of the dorsum of the foot seemed benumbed, cold, and insensible to the touch. Gangrene had set in. The pain was very severe from this time until death, necessitating hypodermic injections to procure rest. On the twenty-seventh day the whole abdomen became distended and tympanitic, the breathing was embarrassed, and the pulse was very feeble and irregular. Strophanthus and strychnine were freely exhibited and the patient rallied and improved daily. The tympanites disappeared, the pulse became stronger, the leg gradually became smaller, and the appetite improved, when on the thirty-third day the right foot began to swell and phlegmasia of that leg developed. The patient thereupon rapidly sank and, refusing all form of nourishment, died on the thirty-sixth day after delivery.

The interest of this case was in the rapid onset of gangrene and the development of phlegmasia in the right leg when the patient seemed to be recovering, as the left leg was becoming smaller and the tympanites had disappeared. There was absolutely no sign of sepsis of the pelvic organs, showing clearly that the illness was entirely due to the feebleness of circulation. This case strikingly illustrates the great importance of careful and prolonged treatment of anæmic patients with weak circulation all through pregnancy and especially during the later months.

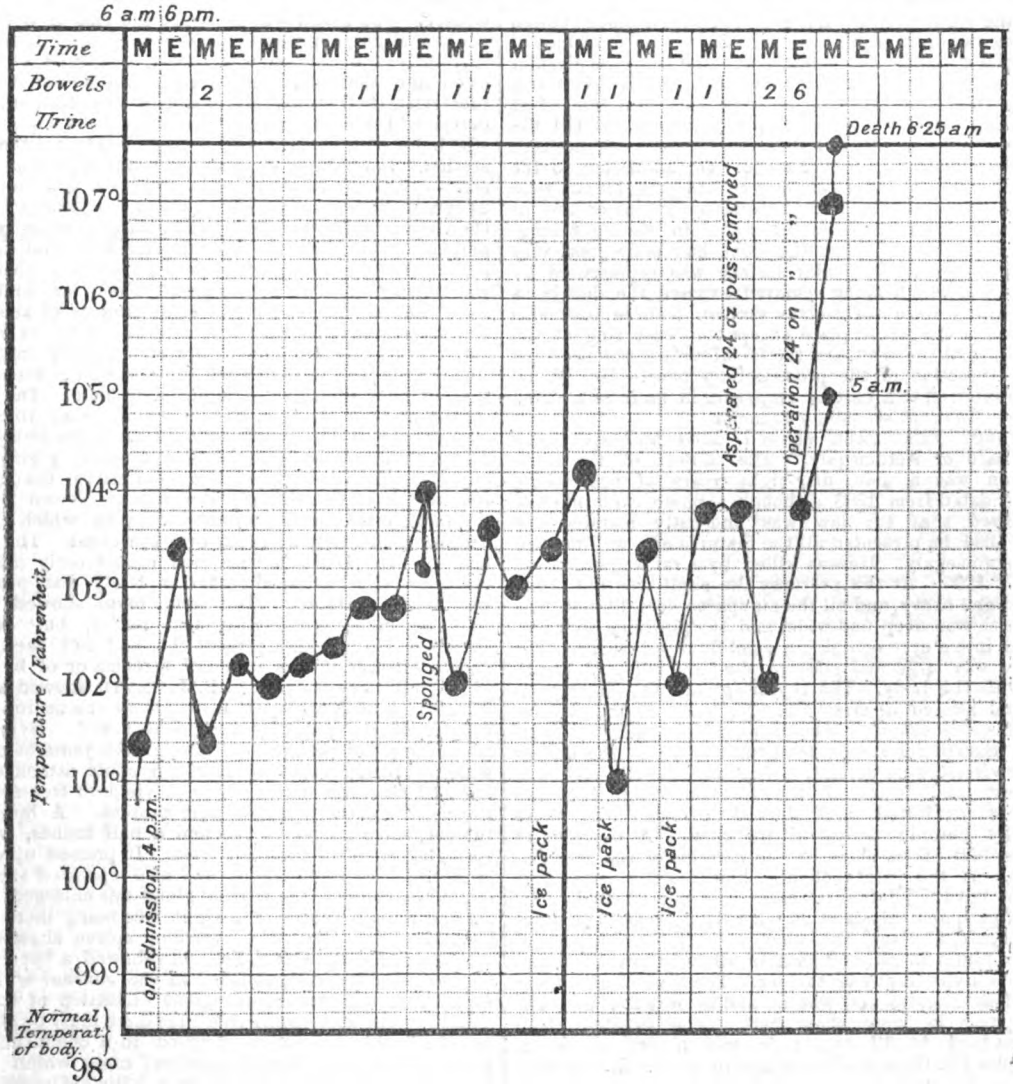
A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum propriis collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.

A CASE OF PNEUMONIA FOLLOWED BY ABSCESS OF THE LUNG, EMPYEMA, AND DEATH WITH HYPERPYREXIA; NECROPSY.

(Under the care of Dr. J. CURNOW.)



FOR the notes of the case we are indebted to Mr. A. E. Griffin, house physician.

The patient, a man aged thirty-seven years, was admitted into the hospital on Sept. 17th with a two days' history of illness, starting with pains in the back and dyspnœa; there was neither cough nor rigor. The patient was stated to have been drinking heavily for three weeks. On admission the temperature was 101·4° F., the pulse was 114, and the respiration was 36. The tongue was furred and white. As regards the lungs, the percussion note was good on both sides anteriorly and on the right side posteriorly. The breath sounds were harsh, but there were no adventitious sounds; vocal resonance and vocal fremitus were normal. On the left side posteriorly the percussion note was impaired from the angle of the scapula, the breath sounds were weak and accompanied by a little dry friction at the extreme base, and vocal resonance and vocal fremitus were normal. The liver was enlarged. The cardiac dulness was decreased, and the sounds of the heart were normal but feeble. On the 18th the temperature was 103°. The patient complained of pain in the left side; the sputum was viscid and slightly rusty. At the left base the percussion note was dull over the lower lobe, the breath sounds were weak with a few râles, and there was coarser friction at the base, this being heard also in the axilla. The urine was acid and of specific gravity 1020; it contained no albumin. On the 19th it was noted that vocal resonance and vocal fremitus were absent over the left lower lobe; the breath sounds were weak and accompanied by much rhonchus—in fact, rhonchus was universal. On the 20th expectoration was typically pneumonic and more profuse, the temperature still keeping about 102 5°; the respiration was 32. The patient was wandering and trying to get out of bed. On the 21st a small patch of tubular breath sounds was noted at the level of the left angle of the scapula; no râles were noted; below the angle the breath sounds were weak, but audible to the base; no friction was heard. On the 22nd, the eighth day of illness, the patient had been delirious all the previous night. The tongue was dry and red. Tubular breath sounds were noted from the apex of the left lower lobe to the angle of the scapula; below the breath sounds were weak to the base. The temperature dropped to 101·2° at 10 A.M. and the respiration fell from 44 to 38. In the evening the former rose to 103·6° and the latter to 50, the patient being still delirious. The temperature gradually rose to 105° on the 23rd and he became somewhat comatose; the ice pack was given for one hour. On the 24th he was in much the same condition, the physical signs were unaltered, the ice pack was again given, and he improved in it. On the 25th he was more comatose and was ice-packed for three hours. The temperature fell to 101° and the respiration from 54 to 44. He recognised people for the first time for twenty-four hours. The physical signs still remained unaltered. On the 26th he sweated profusely, the skin being moist, the face pallid, and the tongue brown and dry. The temperature was 103·3°, the respiration was 54, and the pulse was 104. There was no alteration in the physical signs posteriorly, but some rough pleuro-pericardial friction was noted anteriorly. After consultation with Mr Duffett, the acting principal medical officer, the patient was aspirated immediately below the angle of the left scapula, and twenty-four ounces of thin puriform, odourless fluid were removed. Under the microscope a stained specimen showed pus cells, with staphylococci and streptococci and also a few pneumococci. The

Digitized by Google

condition after aspiration continued to be much the same, the temperature fell from 103·6° to 102° and the respiration from 52 to 44. On the 27th there was much more coma, but the physical signs were unchanged. Mr. Duffett incised the pleura in the eighth interspace in the mid-axillary line, removing twenty-four ounces of pus, and a large drainage-tube was inserted. No anæsthetic was given. The coma increased, and the patient died at 6.25 on the morning of the 28th, the temperature gradually rising to 107·6°, the respiration to 66, and the pulse to 160.

Necropsy.—A post-mortem examination was made on the 29th, when the right lung showed bronchitis and congestion of the lower lobe with some slight recent pleurisy. The left lung showed an adherent pleura in the axilla and posteriorly over the lower lobe. After removal from the body the whole

of the upper half of the left lower lobe was found to be pneumonic. Two inches from the apex posteriorly there was an abscess cavity two inches by one inch communicating freely through a large opening in the pleura with the pleural cavity. The lower part of the lobe was congested, but had not collapsed. No communication could be made out with a large bronchus. The heart showed recent pericarditis with dilatation of the cavities, the liver was fatty and enlarged, the spleen was large and congested, and the kidneys were fibroid. No examination was allowed of the brain.

Remarks by Mr. A. E. GRIFFIN.—Cases of pneumonia followed by abscess of the lung seem to be sufficiently rare to merit reporting. Sturges and Coupland[1] state: "This is a most rare event in the after-history of acute pneumonia; it was found in but one case out of 144 examined after death." The same writers quote Traube[2] as mentioning a case. Wilson Fox[3] also mentions a case reported by Huss. In the case reported above it may be pointed out that though on the fourth day of illness the sputum was pneumonic and on the sixth day typically so, it was not until the seventh day that tubular breath sounds were noted. Again, though on the twelfth day of illness twenty-four ounces of pus were removed, yet even before aspiration breath sounds were heard to the extreme base. The pus removed by aspiration had no odour and at no time was the sputum or breath offensive. The change in the physical signs noted on the seventh day may have been due to the rupture and emptying of the abscess cavity into the pleura, but the physical signs at the base remained unaltered and there were no signs of pneumothorax. That there was some accompanying effusion was recognised, but only after the delay in the crisis, with sweating, coldness of the limbs, and increasing coma, was an empyema suspected.

NURSES' HOME AT BARRY.—At a meeting of the Barry Nursing Association and Accident Hospital, held on Oct. 27th, under the presidency of Mr. G. Neale, J.P., L.R.C.P. Edin., the treasurer announced that nearly £1000 had been subscribed by voluntary contributions for providing a Royal Jubilee Nursing Home for the district in connexion with the jubilee celebration movement. The erection of the building will shortly be proceeded with.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Empyema of the Antrum in an Infant.—Acromegaly—Calcifying Pericarditis.—Salivary Calculus.—Traumatic Neuritis.

A MEETING of this society was held on Nov. 2nd, the President, Dr. PAYNE, being in the chair.

Mr. D'ARCY POWER showed a specimen of Empyema of the Antrum in a Child eight weeks old. The child was admitted into the Victoria Hospital on July 29th, 1897, in a very wasted condition with an abscess discharging at the lower part of the right eyelid. Examination with a probe showed that there was an area of dead bone on the upper surface of the superior maxilla. Pus was also exuding from the alveolar border, but no definite opening could be detected. There was a history that both sides of the face had been bruised at birth during delivery by forceps; but it was not till the child was about a month old that the abscess was noticed. It had been discharging ever since. On admission to the hospital the abscess was freely opened and granulations were scraped away, but the child died thirteen days after, and at the necropsy a small abscess was found in the right lung. The specimen showed that the bone had undergone very extensive necrosis. Its malar surface was represented by two sequestra, which being removed exposed the deciduous molars, which were themselves eroded. There was also destruction of the orbital plate except the dense ring at the lower margin of the orbit, and the facial surface was necrosed up to the junction of the pre-maxillary bone.—Mr. W. G. SPENCER referred to a case of empyema in an infant which he had seen to occur secondary to noma.

Mr. PERCY FURNIVALL showed casts and specimens from a case of Acromegaly. The subject of the communication was a man, fifty-eight years of age, whose symptoms dated from 1893, although a photograph taken in 1875 showed that his jaw was unusually massive. In October, 1894, he presented all the features of a well-marked case of acromegaly. He was killed by a railway engine in December, 1894. At the necropsy the skull was uniformly thickened and heavy, and all the air spaces were dilated. The sella turcica was deep and wide, and the pituitary body was converted into a cyst containing semi-fluid substance. The lower jaw was large and massive, the rami being almost in a line with the body. The thyroid gland was slightly enlarged and altered in structure. No trace of the thymus gland was discovered. The sympathetic ganglia were normal. Except for some interstitial fibrosis of the kidney the other viscera were normal. The clavicle, rib, vertebræ, iliac crest, and bones of the forearm, hand, leg, and foot were exhibited and showed changes like those caused by chronic periosteal irritation. A deposit of new bone had taken place at the margins of the articulations and at the points of attachment of muscles and ligaments, but the joints themselves were not affected. Mr. Furnivall gave an analysis of 34 recorded necropsies on cases of acromegaly, and said that changes in the pituitary gland had been found in all, and that in all but three there had been either hypertrophy or tumour. The thyroid gland was examined in 24 cases and was normal in only five, and was hypertrophied in more than half. The thymus gland was examined in 17 cases; it was absent in seven, hypertrophied in three, and persistent in seven. The sympathetic ganglia were examined in ten cases and were reported as hypertrophied in six of the cases. General enlargement of the brain and of the spinal cord had been noticed, and in four cases there had been degeneration in the posterior columns of the spinal cord. The only constant associated changes appeared to be those in the pituitary body, but it would be noted that these changes were not uniform and might occur without acromegaly.—Dr. ROLLESTON showed the Pituitary Body and Sections of the Thymus Gland from a case of Acute Acromegaly due to Sarcoma of the Pituitary Body. The patient was a woman, aged thirty-five years, who had shown symptoms of acromegaly for three years. She suffered from optic atrophy due to the pressure of the tumour, headache, which was intense at times, and transient glycosuria. The skeletal changes were quite characteristic. The patient had been twice in St. George's Hospital and an account of her clinical case had been published in THE LANCET[1] She died after an epileptiform fit on Aug. 16th, 1897, and Dr. Rolleston performed the post-mortem examination, together with Dr. Hollis, of Wellingborough, under whose care she was. The pituitary tumour was a round-celled sarcoma the size of a walnut and had invaded the right optic thalamus and the cavernous sinus. The thyroid gland appeared normal. The thymus gland was persistent and was much in the condition of that of a child before the changes of involution had set in. Dr. Rolleston considered that the case belonged to the group of acute acromegaly, of which Sternberg in a collection of 125 cases with 47 necropsies had found six examples all due to true sarcoma. The duration in these cases was from three to four years.—Mr. PELHAM LAWRENCE showed the pituitary body from a case of Acromegaly which had been under the care of Mr. Godlee. The gland was of about the size of a cherry and showed slight degeneration of the anterior lobe. Microscopically the change was found to consist chiefly in a swelling of the cells, which were definitely swollen, although preserving their normal arrangement.—Dr. NORMAN DALTON described the microscopic appearances of the organs in a case which he had brought before the society in the previous session. It would be remembered that the patient died with some symptoms of myxœdema and with glycosuria as well as symptoms of acromegaly. There was enlargement of all the viscera. Microscopically the central nervous system was normal. The intestine showed some catarrhal changes to the naked eye, and microscopically the sub-epithelial tissue was thickened as in myxœdema. The spleen and pancreas were normal, but there was some fibrosis of the kidneys. The liver capillaries were full, a few of the cells were fatty, and many were enlarged, showing specially large nuclei. The thymus and thyroid were quite normal, except that the thyroid juice appeared to be unusually fluid. The skin presented marked changes, the epidermis being thinned with hypertrophy of the papillæ and of the cutis vera generally. The papillæ contained irregular clumps of pigment, which appeared to be both in the connective tissue and in the vessels. Dr. Gordon Brown had shown a case of acromegaly to the Hunterian Society in which there was definite molluscum fibrosum over the chest. The pituitary body in Dr. Dalton's case was considerably altered, the posterior lobe having almost completely disappeared. It was much softened. The solid parts showed abundant irregular cells, often with two nuclei, but very little stroma. Up to the present he had not been able to decide whether it was a case of sarcoma or of hypertrophy of the pituitary body.—Dr. E. J. SMYTH showed specimens from a case of Acromegaly in which at the necropsy a large tumour of the pituitary body was found. Symptoms of acromegaly had been present for eighteen years before death, which occurred suddenly from an acute attack of vomiting and diarrhœa which did not yield to treatment. All the usual skeletal changes were present. A large oblong tumour, three inches by two and a half inches, was found springing from the pituitary fossa. It pressed upwards and stretched both optic tracts, and also separated the anterior clinoid processes. The thyroid gland was enlarged, weighing six and a half ounces, the right lobe being more enlarged than the left. Both the liver and spleen showed general enlargement.—Mr. CECIL BEADLES showed a specimen from a case which he had published in the *Journal of Pathology* for 1893 in which there was great dilatation of the frontal sinuses.—The PRESIDENT said that there must be many cases in which this condition occurred in a commencing or a partial form, as well as borderland cases which would be very difficult to differentiate from osteitis deformans. As an example of an early case he mentioned the case of a young, robust woman who was sent up to him. The only changes that he could discover were an enlargement of the terminal phalanges and an alteration of the nails which were becoming at the same time broader and shorter, with a tendency to crack longitudinally.—Mr. BUTLIN said there was as yet no knowledge as to the exact relation between the enlargements of the pituitary body, which appeared to be a constant feature, and acromegaly, since in so many cases of similar enlargement of the body symptoms of acromegaly were absent. He thought that light would be thrown on these cases by the careful study of cases of acute acromegaly such as that described by Dr. Rolleston, and he also thought that most

[1] THE LANCET, April 25th, 1896.

Digitized by Google

careful investigation should be made for any change whatever in the osseous system in every case of pituitary tumour. He had examined the bone in cases of osteitis deformans, and there could be no doubt that the changes were inflammatory. A good account of the minute changes in the bone in cases of acromegaly was much needed.

Mr. C. G. SELIGMANN showed the living ova of Bilharzia Hæmatobium from the urine of a soldier who had recently returned from Mashonaland. The ova were constantly passed from both the bladder and the rectum. Those from the bladder had terminal spines only, while those from the rectum had also lateral spines. The ova could be hatched in warm urine, although not so quickly as in water at the same temperature. In some cases the anterior end of the ovum began to move vigorously, and a number of granules were discharged, many of them collecting between the ovum and the shell. After a time the embryo would become slowly extruded. In other cases the embryo, after more or less active movements within the shell, escapes suddenly through a lateral rent. After escape the cilia at the oral end come to move more vigorously than those elsewhere. The shape of the embryo is constantly changing in an amœba-like manner.

Dr. CALVERT and Mr. T. STRANGEWAYS PIGG showed a specimen of Calcification of the Pericardium the result of chronic pyo-pericardium. The condition appeared to have existed for five years. Three weeks before death the patient was attacked with pleurisy with effusion and died from cardiac failure. The heart was found to be almost entirely cased in calcareous material and there were several ounces of inspissated pus in the pericardium. Such cases were very rare, but had been described by Murchison, Pearce Gould, Laennec, and others.—Dr. A. F. VOELCKER said that there was a similar condition figured by Matthew Baillie in his "Atlas," published in 1803, as one of "ossification of the heart."—The PRESIDENT said that this specimen confirmed his impression that calcification of the pericardium was almost always due to previous suppuration.

Mr. SPENCER showed microscopic specimens of a Submaxillary Salivary Gland altered by general inflammation, the smaller ducts of which were distended by small calculi formed of inspissated mucus in which carbonates were being deposited. The gland had been excised from a girl aged twenty years who had had recurrent distention of Wharton's duct and inflammation of the gland. On opening the duct ropy mucus and numerous small calculi of the size and shape of rice grains escaped. Similar calculi continued to be discharged or were scraped away until finally the gland had to be excised to avoid suppuration. Mr. Spencer mentioned the case of a young man under the care of Dr. Dundas Grant, from whose duct calculi were being discharged of the same size and shape. In the ordinary way a single almond-shaped calculus forms in and fills the main duct. Here numerous calculi arose in the substance of the gland comparable to the formation of calculi in the liver or kidney.

Mr. SPENCER also showed microscopic specimens of Chronic Traumatic Neuritis taken from an amputated leg. The patient, a woman, aged forty-three years, had sprained her ankle severely four and a half years before. She had been under the care of Dr. Ferris, Mr. Davidson, and Mr. Francis, of Uxbridge, and had been several times in hospital under the care of Mr. Spencer. After the accident she could never put her foot to the ground, although all the bruising and swelling cleared up and there had been no fracture or dislocation. She always complained of great hyperæsthesia, of pain especially at night, and suffered intermittently from œdema. After four years ulceration and necrosis of the toes commenced, and the pain spread up to the external popliteal nerve as it turned round the fibula. After the accident the patient developed many general symptoms of a nervous character, and this taken in connexion with the approaching climacteric tended to support a diagnosis of hysteria until this was negatived by the commencing ulceration and necrosis of the toes. Pathologically the case was an interesting one of chronic spreading traumatic neuritis set up by a subcutaneous injury to the soft parts without the intervention of any of the other recognised causes of peripheral neuritis.—Dr. F. E. BATTEN asked if any other stains than the ordinary hæmatoxylin had been employed, and whether during life there had been any reaction of degeneration in the affected limb.—Mr. SPENCER, in reply, said that several stains had been used and showed the same changes. The electrical reactions had not been tested, partly owing to the extreme hyperæsthesia.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

Exhibition of Cases.

AN ordinary meeting of this society was held at 20, Hanover-square on Oct. 27th, Mr. BUXTON SHILLITOE being in the chair.

Mr. W. T. FREEMAN showed a patient, a middle-aged single woman, who had two patches upon her forehead; the edges were slightly raised and were encroaching very slowly indeed upon the surrounding skin. The centre of each patch was occupied by a quite superficial atrophic scar. Neither patch had ever wept, and there was practically no irritability. One patch had existed for sixteen years and the other for twelve years. Mr. Freeman asked for a diagnosis, and the opinions given were various.—An early form of rodent ulcer was suggested by Mr. PERNET.—A specific origin was also suggested, or that the patches were simple lichenous patches.

Dr. ABRAHAM showed in a man about forty-five years of age an interesting example of Xanthoma Diabeticorum. The individual lesions were of about the size of hemp seeds.—Dr. ABRAHAM also brought forward in a man above middle age a case of Granuloma Fungoides. There were well-marked new growths over the lower abdomen and close by the left nipple. The case was originally believed to be one of seborrhœic eczema.—Dr. STOWERS agreed as to the diagnosis and remarked that they seldom had the opportunity of seeing the disease in such an early stage.—Mr. PERNET remarked on the longevity of the ancestors of such patients and gave examples.

Dr. SAVILL showed a case of Urticaria Factitia and also one of Drug Eruption. The urticarial wheals, both those that were persistent and those that could be mechanically produced at the time, were very exaggerated. The drug eruption was marked and not limited to the acne regions.

Mr. SHILLITOE showed a case of Acute General Dermatitis caused by a mercurial ointment.

Mr. HOPE GRANT showed a case of Tumour of the Hand. It commenced a few months previously as a boil; the tumour had steadily increased in size and a scab had formed. It was evidently a tuberculous growth, probably of the nature of a post-mortem wart. The patient was a clothworker.

Dr. ABRAHAM showed for Mr. WAREN TAY a case of Lichen Ruber Acuminatus.—Mr. PERNET called it lichen planus.

Dr. STOWERS brought forward a woman, aged twenty-four years, for diagnosis. He believed it to be a case of Acne Varioloformis.—This was generally agreed to.

Dr. EDDOWES showed a case of Seborrhœa Corporis in a man aged forty-five years. He remarked on the fact of its having commenced on the scalp and then having spread downwards.—Dr. EDDOWES also showed a case of Lichen Planus Hypertrophicus on the legs in an old man.—Dr. EDDOWES also demonstrated by paper, photographs, and microscope a case of Tinea Circinata contracted from a pet hedgehog.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

Exhibition of Specimens.—"Home made" Artificial Denture.—*Extraction of a Tooth by Means of an Elastic Band.*—*A Mandible showing an Embedded Premolar.*—*Acute Suppuration of the Mandible.*—*Presidential Address.*

THE opening meeting of the session of this society was held on Nov. 1st at 40, Leicester-square, Mr. W. E. HARDING, President, being in the chair.

Mr. H. L. ALBERT exhibited two Deciduous Central Incisors which had been removed from the mouth of a child twelve months of age. The teeth presented an extreme development of the cingulum on the palatal side, and as this led to irritation of the tongue the teeth were removed.

Mr. STORER BENNETT showed for Mr. CHARTERS WHITE a specimen of "Home Made" Artificial Teeth. The two central mandibular incisors had been lost and the patient had carved up somewhat primitively two pieces of bone and had fixed them in position by wire ligatures around the adjacent lateral incisors. The specimen shown included the two artificial teeth with the two natural teeth.

Digitized by Google

Mr. G. BRUNTON showed several Instruments of his own design and also recorded a case of Extraction of a Difficult Misplaced Maxillary Bicuspid by means of Elastic Ligatures.

Mr. W. A. MAGGS exhibited a Portion of a Human Mandible showing a first bicuspid embedded in the substance of the bone. The tooth was placed in a horizontal position, the apex being towards the median line the crown being situated just above the mental foramen.

Mr. ROUGHTON read the notes of a case of Acute Suppuration of the Mandible, which was followed by pyæmia and death. The patient was a boy, seven and a half years of age, and on Oct. 1st he sat in a draught at school. The same night he complained of pain in the left side of the face, and on being seen the following day by a medical man was found to have a temperature of 105°F., the gum over the region of the left molar being so swollen and painful that the mouth could not be opened. This condition showed little change for two days, but on the third day rigors occurred, and the following day—namely, Oct. 6th—the swelling had extended into the infra-mandibular region. The patient was also slightly delirious. The next day the swelling having extended further down an anæsthetic was administered and an incision made into the tissues of the neck. No pus was evacuated, but the tissues appeared as if about to slough. The teeth were apparently healthy, but the first permanent molar was quite loose and had pus welling up around it. The tooth was removed and the pus evacuated and the parts rendered as aseptic as possible. The next day signs of peritonitis appeared, the patient dying on the following day. Mr. Roughton considered the case to be one of acute panosteitis. A somewhat similar case was recorded by Mr. Goadby.

The PRESIDENT then delivered his Inaugural Address. He referred to the early history of the society, and remarked that one of the most noticeable features of the period which had lapsed since the foundation was the knowledge which had been obtained of the micro-organisms. After paying a tribute of praise to M. Pasteur and Lord Lister he touched upon the advances made in the knowledge of the micro-organisms of the mouth and their action by Mr. Underwood, Mr. Mills, Mr. Tomes, Mr. Mummery, Mr. Miller, and Dr. Black. He pointed out how our knowledge of the pathology of caries had been advanced by the work of these investigators, and also showed how the adoption of Listerian principles in dental surgery had revolutionised the treatment of septic roots.

At the conclusion of the President's address the meeting adjourned.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE annual general meeting of this society was held on Oct. 23rd, Dr. SEATON, President, in the chair.

The PRESIDENT, after a graceful reference to the recent death and services of Dr. F. W. Barry, delivered his presidential address, taking for his subject the Work of the Medical Societies in its Relation to Public Health. Much of the work of the Pathological, Medical, and Clinical Societies and the unremunerated researches of individuals, whether undertaken in a purely scientific spirit or with an immediate utilitarian motive, had contributed greatly to the promotion of the ends which their society more directly or exclusively had in view. But the Epidemiological Society, which occupied a position intermediate between the strictly medical societies and their own, was above all others engaged, as its objects stated in the charter of incorporation showed, in pursuits identical with theirs. Then there were the British Institute of Preventive Medicine, the Sanitary Institute, the Institute of Public Health, the Jennerian Society, and the British Medical Association, which, though primarily a union of medical men, had a public health section at its annual congresses. The Sanitary Institute and one or two others embraced men of all professions more or less interested in public health, and there was no doubt that much advantage accrued from association with architects, engineers, chemists, geologists, &c., as well as from the museums and exhibitions promoted by some of these societies. Their various transactions and journals were of great value, yet members of their own society who belonged also to the Epidemiological Society and the Sanitary Institute could not but feel that the multiplication of associations involved a loss of the power resulting from union and that, as Sir Douglas Galton had said, "the interest of public health and sanitation were frittered away over too many societies." He would therefore earnestly urge every member of the Society of Medical Officers of Health to do his best to bring about an amalgamation of all those engaged in promoting the same cause, believing that, since the medical element would always be the predominant one, the authority and influence on public opinion of one great society would be far greater than that which they could exercise with their present divisions; and he thought that this year, being the fiftieth anniversary of the appointment of the first medical officer of health, Dr. Duncan, at Liverpool and the inauguration of the public health service, would be a fitting occasion for effecting such a union. He next referred to a number of questions that had long engaged the attention of all really interested in public health, such as the tenure of office, the qualifications of medical officers of health, the severance of public work from private practice, and the relation of sanitary inspectors to the medical officers of health in town and country districts, their qualifications, and the constitution of the court of examiners. In this connexion he could not pass over the able services rendered to the cause of medical officers and public health administration by Dr. Orme Dudfield. The Maidstone epidemic had shown how different was the sanitary examination of water-supplies from the merely chemical question of the analysis of adulterated foods and, also, how important was a knowledge of the normal condition of a given water and of the contingent dangers to which it was exposed apart from actual contamination. Chemical analysis, without bacteriological examination and the other considerations to which he had alluded, might tend to a false sense of security, but taken in conjunction with these it should serve as a delicate barometer and an indication of impending danger. But while such catastrophes aroused public attention owing to their suddenness it ought to be known that there was in some districts a constant prevalence of typhoid fever attributable to other causes than the pollution of a certain public water-supply, and the record and publication of the distribution of any local excessive incidence of this and of other preventable diseases, as was done by the Surrey County Council, by stimulating preventive action contributed in an important degree to the averting of such outbreaks and to the saving of life without the supervention of these terrible lessons. Such a society as he had indicated should include all the leading epidemiologists who, without belonging to the public service, had made the subject of communicable diseases their special study, and its inauguration would, he repeated, be a fitting and worthy commemoration of the jubilee of the institution of medical officers of health.

Reviews and Notices of Books.

The Year-book of Treatment for 1897. London: Cassell and Co., Ltd.

THIS admirable publication fully keeps up the high standard of merit and usefulness which has been maintained in the past. The present is the thirteenth year in which it has appeared. A large part of Dr. Coupland's article on Diseases of the Heart and Circulation is devoted to an able account of the Nauheim treatment, in which all sides of the question are usefully discussed. Dr. Schorstein, who is a new contributor to the work, deals very thoroughly with Recent Advances in the Treatment of Pulmonary Disease; while another fresh contributor, Dr. Francis Boyd, treats of Kidney Diseases and Diabetes. In the section on Infectious Fevers Dr. Sidney Phillips has much of value to say on the Antitoxin Treatment of Diphtheria, and on the Serum Test in Typhoid Fever. Mr. Rose and Mr. Carless treat of the Advances in General Surgery. The subject of Deciduoma Malignum is very fully discussed both in the article on Diseases of Women by Dr. Herman and in that on Midwifery by Dr. Handfield-Jones, and in the latter article the use of anti-streptococcic serum in puerperal septicæmia receives full

Digitized by Google

consideration. Dr. Willoughby deals with Public Health and Hygiene in a series of short but very valuable criticisms, and Dr. Nestor Tirard with the subject of Therapeutics. We have commented on but a few of the excellent articles; most of the contributors are the same as in previous years. We can most heartily commend the annual to every practitioner as an indispensable means of keeping his knowledge of treatment up to date.

Atlas and Essentials of Bacteriology. By Professor K. B. LEHMANN, of Würzburg, and Dr. RUDOLF NEUMANN, of Würzburg. London: Baillière, Tindall, and Cox. 1897. Price 12*s.* 6*d.*

THE larger portion of this little book consists of sixty-three chromo-lithographic plates illustrating the cultural and morphological characters of the principal pathogenic micro-organisms and of a considerable number of the commoner non-pathogenic ones. In so far as it is possible to give any idea of these by chromo-lithography the attempt is creditable enough. In many cases the illustrations give an excellent representation of the cultural characters, especially in instances where the growth is opaque—e.g., staphylococcus albus, bacillus mesentericus vulgatus, &c. Where, however, the growth is of a semi-transparent or fluorescent nature the results are as a rule poor and of little value, for it is absolutely impossible to represent in opaque tints the appearances of a culture of the pneumococcus or the typhoid bacillus. The illustrations are thus of very unequal value. In many cases the appearances of individual colonies as seen under a low power of the microscope are successfully rendered, and the figures of stained micro-organisms are sometimes good. The utility of such an atlas is probably not very great. It is true that occasionally it may give a clue to correct determination, but the absence of any description of the organisms depicted renders verification impossible. For teaching purposes it may serve a good end, where actual specimens and cultivations are not available. The second and smaller part of the book, on the "essentials" of bacteriology is, in our opinion, of far greater value, and many of the chapters will be read with pleasure and interest by those who wish to acquire some knowledge of bacterial chemistry and have no leisure to peruse the larger works on the subject. The morphology and classification of bacteria and the vital conditions necessary to their growth are well summarised. An account of their effects follows, in which the chemical results of bacterial metabolism are considered at some length, especially in relation to the presence or absence of sugar in the nutrient medium. A short appendix deals, in conclusion, with the preparation of staining fluids, cultural media, and other matters of technique. The chemical part of the work appears to us to have considerable value and is well worthy of attentive study.

LIBRARY TABLE.

Under the Red Crescent: Adventures of an English Surgeon with the Turkish Army at Plevna and Erzeroum, 1877–1878. Related by CHARLES S. RYAN, M.B., C.M. Edin., in association with his friend, JOHN SANDES, B.A. Oxon. London: John Murray. 1897. Price 9*s.*—The title of this delightful book should have been "Phil Fogarty II.," for the adventures which the author relates are even superior to the experiences of the Thackeray-Lever hero. Dr. Ryan is an Australian-Irishman and evidently possesses qualities eminently suitable for an army surgeon: indomitable pluck, cheerfulness under the most depressing conditions, and, above all, the quality of sympathy. This latter gift is apparent in his book, so that the reader feels as if he knew the writer intimately by the time he has got to the end of it. Dr. Ryan finished his medical education at Edinburgh University and was enjoying a holiday when he saw an advertisement from the Turkish Government inviting applications to serve as an army surgeon. He at once applied and was accepted, and the first post to which he was appointed was the camp outside Widdin. Of his work here he gives the following picture, the background of which is like an extract from Theocritus:

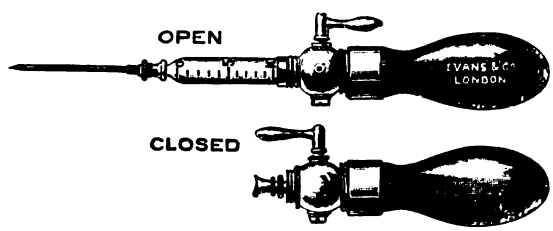
τάχα δὲ κράναν ἐνόησεν
ἠμένῳ ἐν χώρῳ· περὶ δὲ θρύα πολλὰ πεφύκη,
κυάνεόν τε χελιδόνιον, χλοερόν τ' ἀδίαντον,
καὶ θάλλοντα σέλινα, καὶ εἰλιτενὴς ἄγρωστις.

"Half a mile from the camp was a large marsh or swamp, where great white arum lilies grew, with jonquils, narcissus, and the different kinds of iris in magnificent profusion, as well as millions of the tiny white snowflakes. I had a trench dug outside my tent, and once a week our two servants ..... brought back barrowfuls of flowers, which I planted in the trench. Here, too, the orderlies made us a great seat of turf, and every morning, from six o'clock till half-past nine, I sat there among the flowers to receive my patients, who used to come up from the various battalions to have their ailments treated. ..... As I sat on my throne of turf I had a sackful of Epsom salts beside me, together with a bucket of water and a pannikin, so that when the patient had swallowed a handful of the salts I presented him with a pannikin of water and he washed the nauseous mouthful down." Dr. Ryan was soon, however, to see very different work. His account of the Siege of Plevna and of the appalling state into which the hospital got towards the end of that magnificently borne time of trial reads like a chapter from the "Inferno." We must not quote any more, but will only say that after getting out of Plevna Dr. Ryan volunteered for service with the Stafford House ambulance for service in Erzeroum. Here things were, if possible, worse than in Plevna. Typhus fever, cold, and starvation added to the misery of wounds made up a terrible tale. We can sympathise with Dr. Ryan's trials on his journey from Erzeroum to Trebizond, for from a personal experience of the country we know what he must have undergone. Everyone should read this book; it is a plain unvarnished tale of what goes on in war, and takes us back to the simplicity of MM. Erckmann-Chatrian, whose war stories are, we think, superior to those of Zola, except perhaps his "Attaque du Moulin." The style is easy and eminently readable; how much of this is due to Mr. Sandes of course we cannot say, but we are sincerely grateful to both the authors.

The Benin Massacre. By Captain ALAN BOISRAGON, one of the two survivors. London: Methuen and Co. 1897. Price 3*s.* 6*d.*—The author graphically describes the terrible massacre in Benin in the beginning of the present year, the news of which startled the civilised world alike by the act of base treachery of the King of Benin by which it was accomplished, and which was described by the surrounding tribes as a "monkey palaver," not a "man palaver"—meaning to show their contempt that a man could be guilty of such treachery—and by the revolting sight of the human sacrifices and "temples" reeking with human blood which the punitive force that later took the shambles (otherwise the city) found in large numbers in all directions. As one of the only two survivors who escaped the massacre—whose sufferings in their retreat to Gwatto Creek, each with innumerable wounds and their flesh covered with thorns picked up in fighting their way through the bush, must indeed have been horrible—Captain Boisragon is eminently qualified to tell the tale of the incidents, which he does admirably. He also appends a description of the surrounding country and of the events which led up to the outbreak. As a letter of a comrade of one of the victims well puts it, "The loss which the British nation has sustained during the last sixty years through the deaths of so many brave soldiers,

Digitized by Google

bluejackets, and civilians in the glorious work of rescuing the native races in West Africa from the horrors of human sacrifice, cannibalism, and the tortures of fetish worship, must ever be a matter of deep regret and sadness to all, but it cannot fail to make us proud of our countrymen who have nobly and courageously done their duty with the greatest enthusiasm, undergoing hardship and privation inseparable from the trying climate of the West African coast, and exhibiting in their conduct an entire disregard of personal danger."



A new edition of *The Guide to South Africa*, for the use of tourists, sportsmen, invalids, and settlers, has been issued by the Castle Mail Packets Company, and the large amount of information which it contains within the covers of its 400 odd pages and its many maps cannot fail to render it an admirable handbook to those whom it concerns.

The weekly board of the Sheffield Royal Infirmary have issued an interesting souvenir volume to commemorate the hundredth anniversary of the opening of that institution. The historical sketch with which the book opens tells the story of its foundation and development, and the recollections of the medical staff as constituted in more recent years are recounted by Mr. Simeon Snell, F.R.C.S. Edin. A short chapter is devoted to recording the growth of the medical work of the infirmary during the century and another chapter to the biographical notes of the physicians and surgeons who have laboured within its walls. A chronology of events and lists of the various officers, with the dates of their appointments, are also given, together with much other information which will doubtless be of interest to those connected with the institution. The volume is embellished with many illustrations by the autotype and other processes, and is handsomely printed with red borders to each page, and has an appropriate inscription, with Scriptural texts, on the front cover. The many interested in the Sheffield Royal Infirmary will doubtless prize this interesting souvenir of the century's work of their institution.

New Inventions.

A MODIFIED PISTONLESS HYPODERMIC SYRINGE.

THIS syringe is a modification of Koch's, which is too bulky for general use. The illustration shows the arrangement, which makes a very compact and convenient little instrument. It is easily carried in the waistcoat pocket, as it does not take up more room than the ordinary pattern. The stopcock is furnished on both sides with a thread, which screws into a ring, upon which is mounted a cylindrically-shaped elastic air-chamber. To close the syringe remove the needle, unscrew and then reverse the stopcock,

passing the barrel into the cavity of the air-chamber, and screw up. The needle can be inserted into the barrel through the stopcock, being kept in place by a thread screwing into it. This stopcock has a double action, so that when turned to cut off the connexion between the barrel and the air-chamber the latter communicates directly with the outside air. This syringe is very easily rendered aseptic; the piston of the usual pattern is the cause of an immense amount of trouble and frequent delay, while the difficulty of thoroughly cleansing the leather usually fitted is obvious.

The ease with which an injection can be administered with this little instrument is remarkable. It can be prepared for use in a few seconds, and being so simple it cannot get out of order. Absolutely no force is required as there is no piston to jam. If care is taken to turn the stopcock as soon as the upper surface of the solution is seen to reach the point of the barrel marked 0, no air can be injected into the tissues. The fact that this can occur is the only objection to a pistonless syringe, while the advantages are many and quite outweigh this solitary disadvantage which, after all, can only occur as the result of carelessness. The makers are Messrs. Evans and Wormull 31, Stamford-street, S.E.

J. W COCKERILL.
Surgeon-Captain, Army Medical Staff.

THE INDIAN FRONTIER RISING.

THE news from India regarding the campaign against the frontier tribes has now assumed a much better aspect, and there is every reason to hope that the punitive expedition is within comparatively easy reach of a successful termination, although a harassing guerilla warfare may still be expected to follow. The Sampegha and Arhanga Passes have been captured with relatively little loss of life; the passes having been forced the gateway to the Afridi country has been opened, and the "purdah" which has hitherto hidden the comparatively open, picturesque, and fertile country of the Afridi Tirah from view has been raised. The Mullah, Said Akbar, has apparently fled to Jellalabad, and the tribes, disheartened by their want of success, are seemingly now convinced of our power to put down the rising, and as a consequence the revolt is fast waning and the tribes have appealed to the Ameer of Afghanistan to intercede with the Indian Government on their behalf. The Ameer, who has expressed no sympathy with their hostile conduct, appears to have given them some sound and salutary advice and has written to the Viceroy of India expressing his loyalty and proffering all the help in his power. Such is, shortly, the situation at the present time. The home of the Afridis seems by all accounts to be fine agricultural well-to-do country, with plentiful supplies of all kinds, in fact, "a land flowing with milk and honey," and our troops are reported to be in excellent health and spirits. The recalcitrant tribesmen proceeding in the Khyber direction will soon find that they can offer no real resistance to the column advancing from Peshawar. The difficulties of the route have been very great, and the expedition has involved much hardship; the days are still hot, but the nights are very cold. The campaign has been, strategically speaking, well designed and brilliantly executed. We can only trust that Sir William Lockhart will succeed in disarming the Afridis and other opposing tribes and securing a fairly permanent peace. The wounded are doing well, and from all we can learn the hospital arrangements have been good. In the interesting account published in the *Standard* of the 3rd inst. of its correspondent with the Malakand field force, a graphic description is given of the night engagement of General Jeffreys' brigade with the tribesmen. Mention is made of an act of great gallantry on the part of Surgeon-Captain Fisher, I.M.S., who was sent with two dhoolies to the assistance of Captain Ryder's company. He escorted them through the village of Badalai and on to the hill under a hot fire from the enemy. The total losses sustained in the campaign against the border tribes since June to Oct. 28th have been large for frontier warfare. The casualties amount to 247 killed and 843 wounded. This includes 24 British officers killed and 52 wounded. The number of British soldiers killed is 34 and of wounded 151. Among the native ranks 177 have been killed and 595 wounded. These numbers do not include, however, the losses at the Sampagha Pass and the Arhanga Pass or those which have taken place since.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 6, 1897.

THOSE who judge the outlook of the profession of medicine from the side of medical politics may be tempted to take a somewhat gloomy view of the immediate future. The ever multiplying demands of medical education and the ever-increasing torture and uncertainty of the examination processes through which the different medical and surgical qualifications are acquired make the work of the student anxious and exacting beyond all precedent. To practitioners the prospect is little more reassuring. Great judges tell us that the profession has a great future; and certainly their prognosis should be realised. For the scientific basis of all true medical service is being strengthened every day and at every point, and with this the value of medical service should be daily more and more appreciated. Yet experience witnesses almost a daily deterioration in the popular estimate of medical service. To get it charitably or to get it on altogether inadequate terms is the effort of large classes of the community who are not unreasonable in their estimate of other things which they need and for which they are prepared to pay the market price.

It is devoutly to be hoped that this is a temporary state of matters, and that the growth of education amongst us will make the public more intelligent as to the value of true medical service as distinguished from all quack varieties of the same. But how rare is the education that enables men to truly estimate the science and art of medicine. It is notorious that the most cultivated classes have always shown a weakness towards quackery, and the same weakness is not unknown in the more gifted men. No doubt the defects and limitations of medical knowledge have given some excuse in the past for this attitude of mind towards legitimate medicine. But it is daily becoming more and more unreasonable. Of course, medicine still has its limitations. There are whole classes of disease before which we stand very humbly. We are not able to cure them. We can only in a very limited sense control them. Some of them are as yet undefined or unintelligible to the highest medical intelligence. But two considerations are to be urged here. First, that even with regard to those classes of disease medicine and surgery are able occasionally to do wonders in the way of relief of suffering and the prolongation of life, and that with regard to the great mass of human ailment and disease the powers of the medical practitioner are very important and daily becoming more and more so. This much is clear, that on whatever scale the unknown and difficult in matters of disease are in the eyes of the medical man they must loom much larger to him who has not studied medicine or to him who has only studied the arts of deceiving the public with unrealisable pretensions. If the medical man is puzzled by disease and occasionally led into error, how much more must the amateur dabbler in healing go astray.

There are two or three great things for the profession to do to advance its prestige in our ever-advancing civilisation. The first is to complete its own equipment for the contest with disease. The public now are more enamoured of that conception of a medical man which contemplates the warding off or prevention of disease than that which merely removes it. The Chinese idea that medical service consists in preserving health rather than in restoring it has a certain basis of reason in it, and that practitioner will in the long run be most successful who sees in every temporary ailment of his patient the opportunity for advising him against its recurrence as well as the means to strengthen his powers of resistance. Men will be less unwilling to consult their medical adviser if he takes a kindly and yet a scientific interest in the causes which have led to their need of him with a view to such causes being successfully opposed in the future. In other words, the future of the profession is to be advanced by the deepest study of the problems of ailment and disease in all the complicated social conditions in which they arise.

There are, of course, some social or political remedies for the evils which at present depress medical men and destroy medical practice. It is impossible to deny that the profession itself is to blame. It makes itself too cheap. In hospitals it gives itself away too easily to those who could well afford to pay and who would appreciate medicine more if it cost them a reasonable sum per annum as even their beef and their bread—not to say their beer—do. This wholesale treatment of disease in crowds at hospitals has a very injurious effect on medical practice. It compels a reduction in fees which are already inconsistent with justice to the patient or the practitioner. We heard lately of a provincial town in which there was a large outbreak of diphtheria. To the inquiry whether antitoxin was used the ready reply was, "Oh, no, it is out of the question. It could not be paid for."

Even in London, at the very door of the British Institute of Preventive Medicine, the prompt procurement and application of this important medicine are matters which require some ardour and conviction in the practitioner, and if his patient is poor an entire abeyance of the idea of recompense. The recompense of medical service is being so fatally lowered by the competition of hospitals that medical men are discouraged most grievously in the use of the best means. The remedies are largely with the profession itself. The general practitioners of the country have a right to look to their natural leaders, the consultants, for protection from the unfair competition of hospitals, as they have a right to look to all their fellow practitioners in general practice to give no countenance to schemes for sweating medical men and attending the sick in crowds where neither reverence for patients nor attention to their diseases is possible. Another remedy for the low estimate of medical practice is to be looked for in a higher estimate of their disciplinary functions on the part of the qualifying bodies, whether corporations or universities. The medical authorities must often have qualms of conscience when they compare the loose discipline of the medical profession with that of the legal, though life is more than property, and the profession which is meant to cherish and save it should be

Digitized by Google

under still more strict discipline than that of the law. We cannot doubt that these views will force themselves on all who are in any position of responsibility either in the medical bodies or in those great voluntary associations of the profession which have virtually the power to impose laws to regulate medical conduct. But the great security for the lasting dignity of the profession in the eye of the public will be in the determination of its individual members to make themselves familiar with every sound device for alleviating suffering and removing disease.

GREAT interest was evinced in the meeting held last week of the Hospitals Association, and the proceedings justified the interest taken, for rarely has a subject of greater interest been submitted for expert discussion, and not often has the discussion of a great problem yielded better promise of useful results. One thing that was made very manifest at the meeting was that there is very great need of the ventilation of questions such as those treated in the papers read by Sir SYDNEY WATERLOW and Mr. ACLAND. So unused are even the inner public, if we may be allowed the phrase, to the discussion of such questions that at one moment there seemed a danger that the meeting would dissolve without any discussion at all, contenting itself with the passing of a ceremonial vote of thanks. Sir HENRY BURDETT performed a real service by interposing at the critical moment with some effective criticism and setting an example which averted the threatened failure and turned the meeting into a success. But the success of the meeting lay chiefly in its demonstrating that there is much good to come out of such conferences, and we hope that it will be followed up by many more at which people who are interested in hospital work will learn to speak without constraint and to offer and receive criticism in a spirit of unconscious goodwill. The meeting on last Thursday week preserved perfect good humour, but there was manifestly a suspicion abroad that anything like trenchant criticism would probably be resented. We do not for a moment suggest that anybody was to blame for this. On the contrary, we are satisfied that it was nobody's fault and due only to the circumstance that, there being no tradition of outspokenness to warrant any unusual frankness in that gathering, every speaker in his turn felt naturally, and indeed quite properly, unwilling to verge towards anything that might be considered to be personality. This feeling speedily disappears among people who are accustomed to meet for the purposes of discussion, and if the gathering that assembled in the board-room at Charing-cross Hospital under Mr. BONSOR'S presidency could be induced to resume the discussion at the point at which it broke off last week we are convinced that valuable results would follow further conference.

The question which mainly occupied the meeting—namely, the relative merits of the Hospital Sunday and the Hospital Saturday schemes of distribution—is a question of great importance, and it was, perhaps, natural that the meeting should feel a preference for the Hospital Sunday Fund scheme. It has, indeed, much to recommend it. It has been elaborated by a committee that had nothing other to consider than the efficiency of hospital administration as an instrument for bringing charity to bear for the relief of the medical necessities of the poor. The Hospital Saturday Fund Committee has had a somewhat more complicated problem to solve. Charity on one hand and necessity on the other have been the main features of their case. But they have not quite emancipated themselves from the idea that to a greater or less extent they ought to obtain a return for their money, and hence they have appropriated a proportion of their funds to the purchase of hospital letters to be at the disposal of the committee. Such a difference in the point of view necessarily involves a difference in the aspect which the problem of distribution presents and a difference also in the resulting practice. No one method should be proclaimed perfection, nor are we yet clear of the danger that in this, as in other matters,

"..... one good custom should corrupt the world."

But there is another question of even greater moment which received very inadequate treatment at the Hospitals Association meeting—namely, the question of distributing the PRINCE OF WALES'S Hospital Fund. It seemed to be in some way taken for granted that when the question of Saturday or Sunday scheme had been settled the question of the principle upon which this Fund should be distributed would be settled also. That we take to be a very serious mistake. The PRINCE OF WALES'S Fund stands on a different footing and ought to be distributed upon a different principle. Indeed, the materials for discussion as to the methods of its distribution do not yet exist. There is some reason for apprehending that when the hospital accounts of the present year come to be made public it will be found that the PRINCE OF WALES'S Fund has caused some diminution of the subscriptions which ordinarily reach the hospitals direct, and if this surmise should unfortunately prove to be correct it will doubtless be found that the burden has fallen more heavily upon some institutions than upon others. In that case the first duty of those who may be charged with the distribution of the Fund will be to see that any deficiencies traceable to this cause be made good, and only in dealing with the surplus will they be free to entertain considerations of a more general character.

It will thus appear that there is much useful work to be accomplished by a continuance of the conference so auspiciously inaugurated in the board-room at Charing-cross Hospital, and we hope that its promoters will renew their invitation and meet with another equally good response.

CRIMINAL abortion where death of the woman ensues is an offence punishable by forfeiture of life. This is the statute law. In its moral aspect it is held in such general abhorrence that all who are found guilty of the crime—save the unfortunate victim, who is sinner and sacrifice at the same time—are rightly considered as being without the pale of sympathy or commiseration. We have on many occasions pointed out that when the perpetrator of the act is a qualified medical man the sin against GOD and his fellow creatures is the more penal, since he acts under the sordid motive of pecuniary gain. It has been argued, and with some force, that the person who illegally procures abortion has every reason to wish that the life of the woman may be spared

Digitized by Google

and that, therefore, the deed is not committed with malice aforethought, the prime legal distinction between murder and manslaughter. The majority of our judges lean to the side of mercy and direct juries to return verdicts of guilty of the "minor offence," and that, too, in the face of Lord BRAMWELL'S judgment, which has not been over-ruled. Whether we accept the more rigid reading of the Act of Parliament or the milder interpretation matters but little on the occasion of these comments. Little or nothing can be said in extenuation of the professional turpitude of a medical man who engages himself in such nefarious courses. On the other hand we deem it of paramount necessity that the charge should be supported by such corroborative evidence as to leave no reasonable doubt of guilt. When the accused is a qualified medical practitioner the danger of wrongful conviction is greater, inasmuch as the lawful exercise of his calling may be mistaken for criminal procedure.

At the Central Criminal Court on Oct. 30th Mr. WILLIAM ROBERT HALL HAINS, L.R.C.P. Irel., was put on his trial for conspiring with a married woman to procure abortion. We need not go into the details of the grounds on which the charge was based; suffice it to say that the incriminating evidence was supplied by a servant and a young daughter of the female prisoner. How utterly unworthy of credit their testimony was may be gauged by the fact that the jury, after the case for the prosecution had been put before them, expressed the opinion that it should not be carried further. Mr. Justice RIDLEY concurred, and the legal representative of the Public Prosecutor withdrew his support to the indictment. With this episode at the Old Bailey before them our readers may ask, Why did the magistrate commit the case for trial? We consider the action of the stipendiary as consistent with common-sense as it was justifiable at law. A charge so grave could not have been satisfactorily refuted in any other way than by appearance before a high tribunal. But we deeply sympathise with Mr. HAINS in his protracted suffering, for imagination with difficulty suggests the fearful mental anguish incidental to the occasion. To him it will not seem sufficient balm to his wounds that his friends can with fuller heart and surer mind offer him congratulations on his deliverance because of the unequivocal character of his acquittal. This case was a splendid exhibition of even-handed justice. A fellow creature had been arraigned on a charge of the greatest gravity, and judge, jury, and counsel with one voice proclaimed him innocent; for over and above the fact that the evidence was universally deemed insufficient to substantiate the allegations, Mr. HAINS was acquitted without being called upon for his defence, receiving immediately an unconditional release and an unmistakable certificate of an unstained character. But how will this compensate Mr. HAINS for the horrors of the past weeks? We repeat that he has our deepest sympathy. And his experience, also, is one that is incidental to our calling, and only rigorous punishment of false witnesses and blackmailers will prevent such cases from becoming more numerous.

UNIVERSITY OF CAMBRIDGE.—The number of medical students entered as freshmen during the present term is 131, or about 20 less than in the corresponding term of last year.

Annotations.

"Ne quid nimis."

"WHY SHOULD LONDON WAIT?"

THE following words will be read with deep interest by many of our readers:

"I have a great interest in university work. Though I have not myself studied at a university, and have no claims of that kind to put before you, yet, after all, I hope that if I live I may do something to create a university. I believe in the multiplication of these great teaching establishments. That is one of the results of the democracy to which you referred, and a very good result. I am not afraid of the multiplication of these institutions. I think that the experience of Scotland shows that they are not likely to compete in degrading or depreciating the character of the education which they give, and in the United Kingdom our system will not be complete until there is a University in the Midlands."

These words, greeted with applause, were spoken by the new Lord Rector of Glasgow University at a private gathering on Wednesday evening in the course of an interesting speech in acknowledgment of the toast of his health. We need hardly say that we wish Mr. Chamberlain success in his endeavours, but at the same time it is impossible to avoid contrasting the spirit and intention of these remarks with the somewhat lukewarm assistance hitherto rendered by the Government of which he is an influential member to the cause of a teaching university for London. Indeed, if we mistake not, the earlier efforts to obtain such an university were frustrated by the opposition of the provinces and, we think, by Mr. Chamberlain himself. Perhaps it is not too much to expect that the application of the formula of "simultaneity and similarity" may lead to the creation of a metropolitan as well as of a midland university, for it is inconceivable that the overwhelming claims of London to university organisation can be ignored whilst those of Birmingham are recognised. Unhappily for London it has no Mr. Chamberlain to champion its cause.

ILLEGIBLE PRESCRIPTIONS.

MR. LABOUCHERE says that until lately he has been under the impression that all medical prescriptions were written in recognised hieroglyphics and that although they might not be decipherable by the unlearned public they were nevertheless "thoroughly well understood in the trade.' This belief, we learn, has been quite upset by a lady who has told him that this illegibility of prescriptions is "merely due to the bad penmanship of the doctors." It seems that his fair informant has been making inquiries on the subject, and that "from one chemist she got the alarming answer, 'We can generally make out most of it, and *the rest we have to guess.*'" The terrible state of affairs thus so clearly established has had such a disquieting effect on Mr. Labouchere that it has led him, shrewd and practical man though he is, to make a ridiculous suggestion. "My lady friend thinks that the remedy is to be found in typewriters, and perhaps it might be as well if a short Act requiring all prescriptions to be typed were passed at an early date." The lady friend is, perhaps, a "typist" herself, or may be a loyal lady always on the alert to create employment for her own sex, so many of whom are "typists"; but there are no excuses of that sort to be urged for Mr. Labouchere's attitude, while light talk about proposed legislative enactment comes badly from a serious legislator. It is true that a typewriting machine could be carried in a brougham or dogcart, but many modern practitioners go their rounds on bicycles, to say nothing of the army of humble pedestrians, and the least ponderous typewriting

Digitized by Google

machine would be a cumbersome article to carry about by hand or affixed to the framework of a bicycle. Perhaps the fact had struck Mr. Labouchere even in writing, for we notice that in a subjacent paragraph of *Truth* he rather goes back on the proposal that all prescriptions should be type-written by seeing violent virtues in their illegibility. For such is the moral of his next story. Commencing with the reflection that "as a general rule the substitution of one ingredient for another in a prescription is not a matter of any material consequence,"—here the cynical Mr. Labouchere is joking, as he is expected by his readers to joke—he proceeds to relate an anecdote about a valetudinarian of his acquaintance who filed all his prescriptions religiously, and had a most imposing and interesting collection of them. After a time, when he felt in need of medicine he took to using his prescriptions without consulting the practitioner. He prided himself particularly on one of them, which he regarded as an invaluable cure for rheumatism, and as a great favour he one day made a present of it to Mr. Labouchere himself, who speedily discovered that the marvellous specific was simply a mild tonic prescribed by the medical man when his friend was complaining of loss of appetite. Strange to say, the infallible remedy never cured the poor valetudinarian's rheumatism again! "If, however," says Mr. Labouchere, in conclusion, "that prescription had been type-written it would probably never have cured his rheumatism at all, and in that case he would never have had the comfort which he actually derived from it for many years." Observe! not a syllable of regret for so ruthlessly breaking the charm. To some extent we agree with Mr. Labouchere that there are advantages in a patient not being able to read his prescriptions. We are not referring to the possibility of faith-cures, but to the well-known circumstance that many people not necessarily *malades imaginaires* love to develop views concerning their susceptibility to drugs, and to insist that they cannot take this, that, or the other when they know that these particular remedies are being given to them. This playing by the patient at the possession of an interesting idiosyncrasy may seriously hamper the medical man, who is generally driven thereby into Runic characters or Dog Latin.

THE ANTI-TOBACCO SOCIETIES.

ENGLAND is not the only country which fulminates against the use or abuse of tobacco. There is a corresponding French society, and its members have resolved to take time by the forelock, and have already commenced the organisation of a great protest to be put forward at the second congress of the anti-tobacco societies, which will be held in Paris during the exhibition of 1900. The leading spirit of the French society is the President, M. Decroix, from whom we have received the journal of the society containing a preliminary notice of the conference; and without going so far as to endorse his opinion when he says "Tobacco is always useless, often harmful, and sometimes homicidal," we agree with him in so far that we allow tobacco to be sometimes very harmful. It is, of course, a poison; but so is tea, as also coffee—two vegetable products which are consumed by nearly every inhabitant of either England or France. All three can be and very often are abused, but this does not do away with their reasonable use; and, with all deference to M. Decroix, tobacco is not always harmful. On the contrary, in these days of rush and hurry it has often a most soothing and restful effect. The French Society has prepared a series of questions for discussion at the congress, and in the prospectus sent out they invite anyone interested in the question to propose questions upon which they would like the opinion of the meeting. This is a sensible way of going to work, and if we might offer a suggestion it would be that these societies should devote themselves not so much to the getting rid of tobacco altogether, but to seeing that people, however poor, can always obtain pure tobacco. The tobacco sold in France is, to put it mildly, not good, and although in England it is possible to buy fairly good tobacco, it is next door to impossible to get it pure. That is to say, it is nearly always scented or treated in some way so as to give it an artificial flavour. Cigars are beyond the purse of any but a rich man, and as for cigarettes, the filth sold as such is beyond description. A pure tobacco society would be an admirable institution, and as for the traders saying "Customers like scented tobacco," the customer seldom gets the chance of smoking anything else. The truth is that, as in the case of highly-scented tea or soap, it is cheaper to "fake" inferior qualities of stuff than to supply the real thing. To be unsophisticated an article must be of good quality, but the craze for cheapness is ruining everything, and when people buy cigarettes at 1*s.* 11*d.* a hundred it is not to be wondered at that they get—well, an inferior article.

THE CASE OF THE PECULIAR PEOPLE.

MR JUSTICE RIDLEY'S action towards the Peculiar People who were recently convicted in his court was one of great wisdom. While recognising that they had acted for conscience' sake, and therefore refusing to make martyrs of them, he at the same time vindicated the law by requiring them to give sureties for future good behaviour. We congratulate the jury on their verdict of manslaughter, and our congratulations are due not in the least to any savagery in our composition, but to our knowledge that such verdicts are of great use to the public in helping them to distinguish between wholesome independence of opinion and mischievous faddishness entailing misery or worse upon others. If the Peculiar People would confine themselves to dying of their peculiarities it might be logical to say that it was a matter that concerned only themselves; but when their warped and narrow judgment conduces to the death of their helpless children it is time for the law to interfere. Piety is all very well, but when the behaviour which purports to be pious is the outcome of ignorant bumptiousness the would-be pious person must understand that the virtue he aims at will not excuse him for the sins he commits. The Peculiar People neglect their duty towards their neighbour, while their assertion that in so doing they are performing their duties towards God is only their assertion and is authoritatively contradicted by the rest of the world.

ACROMEGALY AT THE PATHOLOGICAL SOCIETY OF LONDON.

THE meeting of the Pathological Society of London on Tuesday last was of a highly interesting character, the main subject being that of acromegaly, to the morbid anatomy of which valuable contributions were made by Mr. Percy Furnivall, Dr. Rolleston, Mr. Pelham Lawrence, Dr. E. J. Smyth, and Dr. Norman Dalton, fully justifying the remark of the President, Dr. Payne, that this was probably the first time that so large a collection of specimens of this rare affection had been exhibited together. Mr. Furnivall, in particular, must be commended not only for the excellent description he gave of his case, but also for the pains he had taken to collect and analyse recorded cases. His statement that in every one of the thirty-four examples he had collected there was some affection of the pituitary body bears out the original observation of Marie, although in the present state of knowledge it is difficult to arrive at a conclusion respecting the relationship existing between the skeletal changes and the somewhat heterogeneous character of the lesions in the

Digitized by Google

pituitary gland. In no inconsiderable proportion, too, the thyroid body was also affected. Dr. Rolleston drew attention to the fact that in the more rapidly advancing cases of acromegaly the pituitary disease was of the nature of sarcomatous growth, a fact which, he said, had been pointed out by Sternberg. This author's monograph[1] is perhaps the most recent, as it is the most systematic, survey of the affection yet published. He distinguishes three types—the benign, which may last for fifty years and lead to but slight discomfort; the ordinary chronic acromegaly, lasting from eight to thirty years; and the acute malignant type, of from three to four years' duration. In speaking of its pathogeny Sternberg says that there are many theories current, and collates them under the heads of: (1) the nervous theory, held by von Recklinghausen and others, but now mostly discarded, that observer's case being recognised as syringomyelia; (2) the theory of atavistic perversion of growth, as suggested by Freund and Campbell; (3) the thymus theory of Klebs; and (4) the pituitary theory of Mairie, who contrasted the disease with myxœdema or cachexia strumipriva. Dr. Dalton at the above meeting advanced another theory—namely, that there was a tendency to general tissue hypertrophy, illustrated in his case by evidences of connective tissue hyperphasia, hypertrophy of the cutaneous papillary body, as well as of the viscera. That disease of the pituitary body may occur without any of the characteristic changes of acromegaly being present was mentioned by more than one speaker; but, as Mr. Butlin pointed out, it would be well in future for those who met with such cases to be careful not to overlook any concomitant changes that might suggest acromegaly. Dr. Payne's remark that cases of acromegaly in its incipient stages must occur, although they may pass unrecognised, is worth noting in this connexion. We may take this opportunity of expressing the hope that the new President's vindication of morbid anatomy as an essential part of pathological science in the admirable address he gave at the opening meeting of the session of the Pathological Society of London will be borne in mind by the members, and that the society will in this respect show greater activity than it has done for the past few years.

[1] Die Acromegalie. By Dr. Maximilian Sternberg. Vienna: A. Hölder. 1897. Price 4 marks 20 pf. This essay forms part of the seventh volume of Nothnagel's "Specielle Pathologie und Therapie" now in course of publication.

THE MAN WITH NO NONSENSE ABOUT HIM.

WITH reference to the cheese-paring policy or total neglect too often prevalent in municipal counsels where sanitary matters are in question a correspondent has sent us a vigorous letter in which the following passage occurs:—

"There are, unfortunately, men so constituted mentally that they hold in utter contempt all knowledge of which they themselves are not possessed or whatever subject fails to interest them. Especially abhorrent to them are matters that do not offer any immediate or visible advantage; indeed, with them everything is to be brought to this precious touchstone to be tested. 'The man with no nonsense about him' is a terrible stickler for justice as applied to others, which, indeed, seems to be all he desires, at least in cases where he may derive benefit from its performance. It is true he always stoutly maintains the necessity for being just before being generous, which axiom he administers as a kind of conscience salve after he has been guilty of a more than usually mean action. Shrewd in all matters concerning things in which he is interested, he shoulders his way to the front in most public questions; fluent in speech, his sophistical arguments often, alas, overrule the sounder opinions of less obtrusive men. In council his great aim is to reduce expense; he thinks he can find much better occupation for his time than in fadding about such questions as drains and sewers or in troubling his head as to the source from which he derives his water-supply. When an epidemic occurs he laments the slow advance of medical and sanitary science, which, in his opinion, should have prevented the outbreak. 'The death-rate is normal,' he will say. 'There is nothing the matter with the sewers,' 'the water-supply is all right.' 'Let sleeping dogs lie,' &c. 'Time enough to spend money upon these things when they are known to be out of order,' howbeit he takes no trouble to inquire as to their condition. It is the influence of these wiseacres in municipal matters that frustrates the efforts of those who would avail themselves beforehand of scientific knowledge and who are sneered at as cranks and faddists. With what results full many a town can testify. For the sake of some trumpery present economy a whole district is exposed to the ravages of avoidable disease, with all its attendant misery and desolation."

Our correspondent deprecates any reference in his remarks to persons or to particular and recent calamities, but asks whether the picture he has drawn does not constitute "an easily recognised and all too common type." To this question we have to say that we consider that in "the man with no nonsense about him" he has depicted very accurately a person with whom all medical men are familiar—and disgusted.

THE CERTIFICATE NUISANCE.

THE question of hospital practitioners charging fees for filling up and signing certificates required by patients for making a claim on insurance and other club funds has been raised by a patient at St. Thomas's Hospital. In this instance a fee of 5*s* was claimed and paid. This claim was based on a misapprehension on the part of the medical officer concerned and was not made with the sanction or knowledge of the hospital authorities. Steps have at once been taken for the prevention of such an occurrence in the future. At the same time it should be clearly understood that a printed certificate of attendance at the hospital and of inability to continue his work is of course given to any patient who asks for it. But the question has arisen concerning insurance certificates, some of which are extremely elaborate and demand much time and thought in their preparation. They are increasing in number, length, and complexity. The whole question is one which must receive careful consideration so that some uniform method of dealing with them may be adopted at all the general hospitals.

THE CHEMISTRY OF THE CEREBRO-SPINAL FLUID.

THE composition of the cerebro-spinal fluid has been investigated by various chemists both in man and the lower animals, but without satisfactory results, partly perhaps because it has been examined not in healthy but in diseased conditions. The presence of a cupric-oxide reducing substance has been generally admitted, but whilst Halliburton observes, in the last edition of "Kirkes' Physiology," that it contains besides salts and proteids in solution, a substance which gives Trommer's test for sugar, it is, however, he goes on to say, not sugar, but a substance of the aromatic group called pyrocatechin. Hammarsten, however, in his "Physiological Chemistry," admits a copper oxide reducing substance and describes it as an optically inactive but "fermentable" substance, a statement that is not compatible with its being pyrocatechin. With the object of reconciling these differences Dr. E. Nawratzki, of the Dalldorf Asylum for the Insane, has undertaken an investigation upon the fluid in the lower animals and in man. He adopted the plan of making a Quincke's lumbar puncture, by which means absolutely pure liquor cerebro-spinalis can be obtained, and his first researches were made upon the calf. The mode of slaughter practised on these animals was favourable to the inquiry. Oxen, sheep, and pigs, on the other hand, could not be used because they were killed in a manner which rendered the procurement of the

Digitized by Google

pure fluid difficult or impossible. From the calf he obtained from 20 to 60 c.cm. of the fluid contained in the sub-arachnoid space. The fluid was limpid and colourless, of slightly saline taste, and contained neither flocculi nor coagula. Under the microscope isolated red and white blood corpuscles were frequently visible, probably driven in by the needle. The fluid was feebly alkaline and became opalescent on boiling. On the addition of a small quantity of acetic acid a finely flocculent precipitate was thrown down. On the addition of solution of soda and a trace of copper sulphate in seven out of twenty experiments a slight violet coloration was observed; in the remaining thirteen there was none. In all instances a positive result was obtained by the use of Trommer's test. No response was obtained from Nylander's test. In the cases in which the phenyl-hydrazin test was applied the results were positive. The doubtful and conflicting statements of writers in respect to the nature of the reducing substance Dr. Nawratzki believes to be due to the small quantity of fluid at their disposal. He accordingly mixed the fluids obtained from no less than 85 calves, and thus collected more than two litres, which were acidified with acetic acid and mingled with a considerable quantity of alcohol. The mixture was then divided into four portions. These were severally tested for a copper-reducing substance and for pyrocatechin, and the results of his experiments were that in opposition to Hoppe Seyler and Ransom he finds that in health a substance is present which in all its properties agrees with grape sugar. The percentage amount is smaller than that in blood, varying in different classes of the animal kingdom from one-tenth part to two-tenth parts per cent., whilst pyrocatechin is entirely absent.

A NEW LOCAL ANÆSTHETIC.

OF the making of new local anæsthetics there appears to be no end. The latest claimant rejoices in the name "p-amido-m-oxy-benzo-methylic ether." The German chemists, Einhorn and Heinz, who have experimented with this substance have adopted for it the more convenient term "orthoform." It is a white crystalline powder and is without odour or taste; it is but slightly soluble. However, it forms soluble salts with acids which, while they possess distinctly anæsthetic properties, are rather irritating when applied to mucous membranes. The powdered orthoform placed upon the surface of an ulcer or inflamed mucous membrane produces, it is said, insensibility of the part and its anæsthetic action persists for some time. It possesses the advantage of being non-poisonous, and so can be freely applied to the surface of burns and painful cancerous and other ulcers. It has been given internally in gramme doses in cases of gastric carcinoma. Its insolubility appears to be a drawback to its employment as a local anæsthetic for surgical work, but successful results appear to have followed its use at Munich for surgical operations.

FREE SHOOTING.

MATTERS in the County of London are rapidly approaching the happy state of things which used to exist in California and Australia in the "fifties," when the custom of shooting on sight was looked upon as laudable and justifiable. Four cases of shooting came before the courts on Nov. 2nd, another one on Nov. 3rd, and it has become quite a common thing for gangs of boys aged about fifteen years to perambulate the East End and Clerkenwell armed with revolvers. When these gangs meet there is trouble. Statements have appeared in the lay press to the effect that ten cases of shooting have been attended to at the Royal Free Hospital within the last ten months. This is a slight exaggeration, the correct number being eight up to Oct. 31st. Unfortunately education as given in elementary schools where we suppose these enterprising youths have been brought up does not as yet include revolver practice, so that harmless passers-by are often hit and sometimes killed. If only members of the gang suffered no one would object. Seriously though the custom must be put down at all costs. A licence to sell pistols or revolvers should be made to cost a large sum and a licence to carry one still more. The sooner the defunct Pistols Bill is brought in again and passed the better, for it is perfectly intolerable that in the greatest city in the world and after nearly thirty years' working of the Education Act a state of matters should be allowed worthy only of a frontier settlement. The magistrates, also, are much to blame for the ridiculously inadequate penalties they inflict when an offender is brought up for punishment; retribution, heavy and swift, should follow any case of shooting in the streets, except perhaps in the very exceptional case of the use of a revolver by a policeman.

THE EPIDEMIC OF TYPHOID FEVER AT LYNN.

THE outbreak of enteric fever at Lynn still progresses. Already the attacks number about 300, and some ten fresh cases occur daily. There can be but little doubt that the washing of filth into the Gaywood river, whence the corporation derive their water, is the cause of the outbreak, just as it was in 1892. Unfortunately, too, the ratepayers are themselves responsible for the large amount of disease which has occurred, for a majority of them persistently opposed new waterworks, and at last the Local Government Board had to intervene with a peremptory order. The delay occasioned by the townspeople prevented the new works being available before the beginning of this epidemic. Dr. Frederick St. George Mivart, of the Local Government Board, has been for some days past conducting an inquiry into the causes and means of spread of the disease. Our Special Sanitary Commissioner is making a detailed report for our readers, the first instalment of which will be found on page 1218.

THE BACTERIOLOGICAL EXAMINATION OF THE BLOOD.

IN recent years bacteriological examination of the blood during life has become more frequent. The *American Journal of Medical Sciences* for October, 1897, contains a summary of the results obtained by Dr. John Slade Ely. As a diagnostic aid such examinations have proved disappointing; the proportion of cases in which positive results are obtained is very small. As a means of throwing light on pathology, on the contrary, they are very valuable, explaining the occurrence of complications in diseases which usually are localised. Pyogenic germs have been detected in the blood during life in pyæmia, osteomyelitis, puerperal fever, erysipelas, and infective endocarditis; the pneumococcus in pneumonia and infective endocarditis; the bacillus coli communis in cystitis with a pyæmic condition; the gonococcus in infective endocarditis following gonorrhœa; the tubercle bacillus in tuberculosis; and the typhoid bacillus in typhoid fever. Some investigations by Kohn published in the present year are of great interest. In pronounced sepsis a positive result was always obtained, and in some cases the bacteria were present in large numbers. In a case of acute ulcerative endocarditis plate cultures of the blood yielded 200 colonies of streptococci and several of staphylococci. In 32 cases of pneumonia a positive result was obtained in 9. Of the latter 7 were fatal, and the 2 which recovered were complicated respectively with pneumococcus empyema and pneumococcus abscesses. Of the 23 negative cases 18 recovered. Of the remaining 5 the fatal result was due in 2 to secondary

Digitized by Google

streptococcus infection (empyema); the patient was alcoholic in 1; and the pneumonia was probably due to the influenza bacillus in a fourth. The high proportion of positive cases—28 per cent.—is very remarkable; so, also, is the prognostic significance of the presence of the pneumococcus in the blood, foreshadowing death usually, or, at any rate, complications, and its absence the opposite at least in cases of pneumococcus infection. In the Johns Hopkins Hospital *Bulletin* for June, 1897, Dr. E. Block relates a fatal case where the typhoid bacillus was obtained twice during life from the blood of the patient. In most cases such attempts fail. As the bacillus can, as a rule, be cultivated from the internal organs after death the writer infers that it must be present in the blood at some period during life in nearly all cases. We pointed out the fallacy of this mode of reasoning a short time ago in dealing with the subject of typhoid cholecystitis[1]—a criticism which the striking difference as regards extent of infection between the fatal and non-fatal cases of pneumonia shown above amply justifies. But the facts now published carry us further, and suggest for the infections in general the question (not to say conclusion)—Are not the cases which show infection of the blood the severe and the fatal ones, and those in which the blood is free milder and more prone to recovery? The usual failure of the blood-examination as a means of diagnosis is explained by this suggestion.

NURSING IN IRISH WORKHOUSES.

IF all that has been revealed during the last year or so stands the test of thorough investigation it is high time that the Irish workhouses were set in order, and we are therefore glad to find that a General Order of the Local Government Board has recently been issued bearing the same provisions as that for England, to which we recently adverted. If it is necessary in the case of the English workhouses it is still more so in the case of the Irish ones that paupers should cease at once and for ever to act in the capacity of nurses, and this necessary reform is made quite clear in the Order. We are glad also to find that paupers cannot be deemed qualified to act even as *attendants* in the sick wards without the previous sanction of the medical officer, and that the nurse is to take her orders directly from the medical officer as to the nursing of the sick and ventilation of the wards and so forth, instead of his orders being subject to the revision of the matron as heretofore. This new order also makes the very useful provision that the medical officer can demand extra nurses in times of stress of work or epidemics, and the master, who in small country workhouses is often only an ex-gate porter, is not allowed to exercise any discretion in the matter, but is to supply the extra nursing demanded. These provisions will certainly be very great gains—that both medical man and nurse shall be less fettered in matters medical and nursing. There are, however, two somewhat serious defects in this as in the English order. In the first place the term "trained nurse" is not clearly defined, or it would perhaps be more correct to say is imperfectly defined. Persons are said to be eligible for the post of superintendent nurse when they have "undergone for three years at least a course of instruction in the wards of a hospital or infirmary being a training school for nurses" (and recognised as such by the Local Government Board). It follows from this that although a person may be deemed by the authorities at the school where she was trained not sufficiently qualified to receive a certificate after examination at the end of her three years' training, she is nevertheless qualified to act as a superintendent nurse! Would it not have been better to word the Order to the effect that the nurse should have obtained a certificate of efficiency at an examination after three years' instruction at a recognised school of training? Again, in accordance with the present phrasing, many of the excellent nurses trained by the Workhouse Infirmary Nursing Association would be ineligible for the post of superintendent nurse, though they have often had much better training than some of those who are eligible for the post under the new Order as it now stands. Another difficulty which is bound to arise under the new Order will be that of procuring sufficient nurses who have been properly trained; and if the association gives up its good work, as seems likely if rumour be true, it is difficult to know where the nurses are to come from. Guardians had sufficient difficulty in former times in procuring trained nurses, but now their difficulty will be tenfold, and the sooner this question receives the consideration of the authorities the better. We fear the new Order will foster the tendency there is for every small workhouse infirmary to multiply its "*assistant* nurses" at the expense of efficient persons, and thus to turn itself into a training school, as it were. We cannot help thinking that this Order, like the English one, has been framed without sufficient advice from experts learned in matters medical and nursing.

[1] THE LANCET, June 12th, 1897.

THE PAYMENT OF CORONERS' JURIES.

IT is in the air that coroners' juries shall be paid at last, which will be glad tidings, not only for persons who are summoned on coroners' juries, but for that wiser section of the public which does not mind paying a trifle in return for valuable services. The Public Control Committee of the London County Council recently reported to the Council that they have come to the conclusion that any scheme which attempted to make class distinctions would be futile, and that they are of opinion that payment of a fixed sum to all jurymen should be made. They considered that 2*s.* for each attendance would meet the case fairly, and they estimated the average attendance of jurors at fifteen, making an annual cost to the County of London of about £7000. The report was referred back to the Public Control Committee to consider the question of raising the fee. The coroner's inquest rightly conducted is a valuable proceeding, and there is no reason why the jurors who are engaged in safeguarding all our lives by sitting on these inquiries should give their time and services for nothing. We hope and believe that the Council will take this view.

EMBOLISM OF THE SUPERIOR MESENTERIC ARTERY.

THE symptoms in the following case recorded by Dr. Karcher, of Basle, and published in the *Journal des Praticiens* of Oct. 23rd, 1897, are very characteristic of embolism of the superior mesenteric artery. A woman, aged forty-one years, with mitral obstruction, dilated heart, and failing circulation, entered a hospital. She improved under rest and digitalis. But on the evening of the third day she was suddenly seized with violent abdominal pain below and to the left of the umbilicus, and a little later with pain in the left leg. At the same time bloody motions came on. There were cyanosis and dyspnœa; the pulse was almost imperceptible; the extremities were cold and covered with clammy perspiration; and the temperature was 35·6° C. However, she revived after injections of caffeine and camphorated oil. On the following days the abdomen remained tender, but no ascites was present. Gangrene occurred of the left leg, which was amputated at the end of five weeks. The popliteal artery was found to be blocked by a thrombus. After eight days the patient succumbed to progressive failure of the circulation. At the necropsy the heart was found to be very dilated with thrombosis of the left auricle, mitral obstruction and insufficiency, aortic obstruction, and tricuspid insufficiency.

Digitized by Google

There were infarcts in the lungs, kidneys, spleen, and liver. At its origin the superior mesenteric artery was obstructed by a thrombus with a ramification in a pancreatico-duodenal artery. In the middle the thrombus was softened and suppurating, and communicated by a perforation in the vascular wall with a large pancreatic abscess. Probably the ischæmic pancreas had been infected from the intestine. The survival of the patient for almost two months is exceptional; cases of embolism of the superior mesenteric artery usually succumb in a few days.

THE PLAGUE IN INDIA.

WE are glad to learn from the Indian papers by this mail that there has been a satisfactory improvement in the health of Bombay during the week ending Oct. 16th, but the latest telegraphic intelligence states that there has been an increase of plague at Poona where the deaths are reported to number nearly 100 daily. Outbreaks of the disease have also occurred at Sholapore, Kankhal, and one case is reported at Madras. At Poona, in addition to the patients in the Hindu and Mohammedan plague hospitals, there are many in the cantonment hospitals and several Europeans have been attacked with the disease.

HOURS OF RAILWAY SERVANTS.

IT is with pleasure that we note in an introduction to the Report of the Board of Trade on its work under the Railways Regulation Act, 1893, for the year ending July, 1896–97, that Sir Courtenay Boyle is able to testify to the willingness of the companies to listen to the representations of the Department. The number of complaints also show a marked falling off, the figures for the past three years being as follows: 1894–95, 156; 1895–96, 97; 1897–98, 76. The danger of overworking railway employés, especially signalmen, has been demonstrated practically by many an unfortunate casualty, and it is gratifying to know that the Act is serving as a check to a state of things which was a menace to the lives of the public as well as an injustice to the railway servants. The number of hours worked in some cabins we still consider far too long, and we hope that the next report will show that an improvement in this direction has been made.

THE SPINAL CORD IN PERNICIOUS ANÆMIA.

AN important paper on this subject appeared some time ago in the *Nordeskt Medicinskt Arkiv* by Dr. Petrèn. He had examined the spinal cords in nine cases of pernicious anæmia, and in two of these, besides the usual symptoms of anæmia, there were also symptoms of an affection of the spinal cord. In four of the cases the vessels of the white substance of the spinal cord were affected with hyaline degeneration which could reasonably be regarded as a result of the cachexia. In five cases were found scattered small hæmorrhages in the cord, or sclerotic patches the result of such hæmorrhages; these are comparable to the hæmorrhages found in the retinæ in this disease. In two of the cases in which clinically no symptoms of affection of the spinal-cord existed the posterior columns showed a chronic degenerative change. Of the two cases with symptoms of spinal-cord disease the first was that of a woman, aged thirty-six years, whose anæmia had lasted six months, and in whom the symptoms of affection of the spinal cord had been present for two months. These symptoms consisted of motor and sensory impairment in the limbs, ataxy, loss of knee-jerk, and in the later stages incontinence of urine. In the cord the posterior columns were much affected, the columns of Goll being almost completely degenerated, those of Burdach rather less so, the degeneration becoming less marked from below upwards. In nearly all the dorsal cord and in part of the cervical, the peripheral part of the cord except the zone of Lissauer was much affected, apparently by a somewhat acute destructive process. The second patient presenting spinal symptoms was a man, aged forty-two years, who had paralysis, gradually increasing, of his lower limbs, which began three years before his death. There was a spastic condition of his legs, but the condition of sensibility was not ascertained. In the spinal cord there was found widespread degeneration of the columns of Goll and Burdach. The right crossed pyramidal tract was also degenerated. In all cases of this description Dr. Petrèn says the fibres of Goll are probably first attacked in the cervical region. Later the columns of Burdach suffer, but the zone of Lissauer is spared. After the posterior cords the lateral are next attacked, and the affection may also spread to affect the anterior columns. Dr. Petrèn also examined the spinal cord in two cases of Hodgkin's disease, but found no alteration except that there were a few small hæmorrhages present.

THE LATE SIR RUTHERFORD ALCOCK.

THE distinguished diplomatist who passed away upon Nov. 2nd was, we are proud to say, a member of our own profession, as was also his father, Dr. Thomas Alcock. On completing his medical education he entered the marine brigade of the British auxiliary forces which were fighting in the Carlist and Miguelite wars in Spain and Portugal. After being appointed Deputy-Inspector-General of Hospitals he retired from the medical profession and entered the diplomatic service. Of his long and useful career in China and Japan we need not speak here, except to say that for over thirty years he served his country faithfully and well. No doubt his medical training, a training which braces up the faculties of observation and the power of drawing accurate deductions, stood him in good stead during his after-career; and like that other great medical diplomatist who is still with us, Sir John Kirk, he opened up countries practically unknown to Europe so that his own country was enabled to benefit by fresh fields of commerce, while at the same time neither administrator made the mistake only too common in some parts of the world of trying to alter or do away with harmless customs merely because they were strange to an European eye or mind. Men of this class are very builders of Empire, and happy is the country who has such at her disposal.

NERVE-DEAFNESS IN DIPHTHERIA.

AFFECTION of the labyrinth or auditory nerve in diphtheria is of the greatest rarity; it is unmentioned by almost all authorities. The following case is described by Dr. J. C. Wilson in the *American Journal of Medical Sciences* for October, 1897. A woman, aged thirty-three years, complained of sore-throat. The tonsils were covered by a dense, greyish-white exudation with abruptly margined borders, surrounded with hyperæmia. On the fourth day there were distressing tinnitus and loss of hearing, which latter became total on the next day. Antitoxin was injected, and the membrane disappeared in the course of two days. The tympanic membranes were bright red, but glistening and not bulging. Bacteriological examination failed to show the bacillus. On the ninth day there was loss of power of the muscles of the back of the neck, and later double vision and paresis of accommodation ensued. The patient gradually recovered and the membrana tympani became normal, but the tinnitus continued. Deafness was absolute with all tests. Six months after the attack the deafness, tinnitus, and slight vertigo persisted, as well as paresis of the muscles of the neck. Dr. Wilson suggests that the

Digitized by Google

failure of the bacteriological diagnosis may have been due to the previous use of antiseptics. He fairly insists that the condition of the throat, the rapid disappearance of the membrane after the use of antitoxin, leaving superficial erosions, and the pareses justify the diagnosis. The deafness was probably due to labyrinthine lesions. Moos, on examining the bodies of three children who died from diphtheria, found the membranous semicircular canals filled in many places with coagulated lymph, whilst the middle ears showed merely catarrhal changes.

THE LATE PROFESSOR HAUGHTON.

AMONG intellectual Irishmen few were more prominent and typical than Professor Haughton, M D. Dub., D D He was encyclopædic in his knowledge and his conceptions of knowledge. Divinity, mathematics, mechanics, physics, physiology, languages, medicine, all seemed alike easy to him. But it was in his nature and disposition that his chief charm lay. His geniality and humour were constant and sometimes irrepressible, even when subjects of grave moment were under discussion. He was a very familiar and distinguished figure in the General Medical Council on which for a great many years he represented Trinity College, Dublin. On questions of education, especially general education, he spoke with an authority to which no other member could pretend. But on essentially medical subjects, such as midwifery and infectious diseases, he spoke well and was always on the practical side, as one representing a country the social condition of which made medical help at once difficult to get and essential to have. Professor Haughton was for years on the Education Committee of the Council, and in this capacity he did great service. Proud of the great College of which he was so distinguished a representative, and ready as he was to fight for her whenever anything was said which seemed to conflict with her interests or her honour, he yet concerned himself with all the ordinary questions which engaged the attention of the Council both in its educational and its ethical work. And so it happened that when failing health compelled his reluctant resignation the members felt an unusual personal sense of loss and regret and that one would be missing from their midst who imparted to their discussions interest and wit and learning of quite an exceptional kind.

As recently intimated in our columns Sir William Gowers is to be entertained at dinner by the Society of Medical Phonographers. The occasion of the dinner is to congratulate Sir William Gowers on his knighthood, and although the members of the society have felt that the occasion affords them a peculiar opportunity for recognising the services which Sir William Gowers has rendered to the society, it is hoped that it may have a somewhat wider significance as a recognition of the debt which the medical profession in general owes to him. The dinner is to take place at Limmer's Hotel, George-street, Hanover-square, on Nov. 25th, at 7.15 for 7.30 P.M., and Sir William Broadbent is to occupy the chair. Anyone who wishes to be present is requested to apply to Mr. L. E. Creasy, 1, Windsor-road, Ealing, W., or to Dr. James Taylor, 49, Welbeck-street, W., from whom tickets (price 10*s*., exclusive of wine) may be obtained.

AT the meeting of the Clinical Society of London to be held on Friday, Nov. 12th next, a series of cases of Forcible Rectification of the Deformity in Pott's Disease of the Spine will be brought forward by Mr. A. H. Tubby and Mr. Robert Jones. Dr. Calot, the introducer of the method, will be present, and no doubt the cases will be subjected to full discussion.

THE November dinner of the Aberdeen University Club, London, will be held at the Holborn Restaurant on Wednesday, Nov. 17th, at 7 P.M. Dr. Robt. W. Burnet will take the chair, and intending diners should communicate with the honorary secretaries, Mr. J. Gerald Laing and Dr. James Galloway, at 54, Harley-street, W.

THE QUEEN has been pleased to give and grant unto Mr. Philip Demech, M.D Edin., licence and authority to accept and wear the insignia of Chevalier of the Order of Orange-Nassau, which the Queen Regent of the Netherlands, in the name of Her Majesty the Queen of the Netherlands, has conferred upon him in recognition of his services whilst actually and entirely employed beyond her Majesty's dominions as Dutch delegate on the Egyptian Conseil Sanitaire, Maritime et Quarantenaire.

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

XVIII.[1]

NEW RIVER COMPANY—*Continued.*

PRESENT CONDITION OF THE NEW RIVER—A SURVEY.

THE New River was originally made to convey water from the springs of Chadwell and Amwell to London. The total length of the river when first made was just under forty miles. This distance has been considerably lessened, short cuts in a more direct route having been made over some of the valleys. At first only spring water was conveyed, but after a time the amount proved to be insufficient and an extra supply was taken from the River Lee.[2] Of late years a number of wells have been made near the banks of the river and the water is pumped to augment the quantity which comes from Chadwell spring and from the Lee. In a few instances water is pumped direct from the wells for the supply of customers, but the greater part is pumped into the river and goes to Newington where after passing through the subsiding reservoirs it is filtered before distribution. The width of the New River varies from about 25 ft. in the widest part to 17 ft. in the narrowest.

Before describing the course of the river it may be well to give a brief account of the work which has to be done to keep it in order and of the way in which it is protected. The general work which has constantly to be done is that the banks of the river have to be kept in a good state of repair, the weeds which grow in the stream have to be cut, and trespassers have to be prevented from doing any damage to the water or to the banks. In order that these things may be efficiently carried out the river is divided into twelve divisions or "walks." Each walk is under the care of two men, the senior of whom is called the "walksman," and the assistant the "walksman's mate." It is the duty of these men constantly to perambulate the river to keep off all intruders, man and beast, to repair the banks where necessary, and to cut the grass on the walks which extend on both sides of the greater part of the course of the river. It may be interesting to mention as a curious matter of etiquette which has lasted a long time that it is usual for the walksman to look after the right or "upper bank" of the river as it is called and for the walkman's mate to look after the left or "lower bank." This custom is a constant one. During the

[2] In this article the spelling of the Lee adopted is that given in various Acts of Parliament. Cartographers, including those employed in Her Majesty's Survey Office, usually spell the Lee—Lea.

Digitized by Google

summer a good deal of work has to be done in keeping the river free from weeds and for this purpose extra men are employed. From May to September weeds have to be cut about once a fortnight. The river weeds grow much more freely at the upper part of the river—that is, the part distant from London—than they do at the lower part. It may be noted, however, that the American weed grows only in the lower part. Above Hornsey it is hardly to be seen and at the upper part it does not occur at all. The way in which the weeds are cut is as follows. Several scythes, from eight to twelve in number, are shackled to a chain to each end of which a rope is fixed. One man walks on each bank of the river and the weeds are cut by a sawing motion, both men walking slowly forwards and each man alternately pulling his end of the rope towards him for a distance of about a yard. After the weeds are cut they float down and are collected by gratings placed across the river at intervals; they are removed from these and usually taken away to manure the land.

Each walk is provided with a punt, which is used not only when it is necessary to repair the banks of the river, but for carrying any materials which may be required for repairs. The punts are of uniform pattern. They are made of iron, and are 30 ft. in length, 2 ft. in depth, and 6 ft. in breadth.

The walks into which the river is divided are numbered from Clerkenwell upwards to Chadwell, and are as follows: (1) New River Head to Stoke Newington, (2) Stoke Newington to Hornsey, (3) Hornsey to Bowes Park, (4) Bowes Park to Winchmore Hill, (5) Winchmore Hill to Enfield, (6) Enfield to Turkey-street, (7) Turkey-street to Theobald's-lane bridge, (8) Theobald's-lane bridge to Turnford, (9) Turnford to Broxbourne, (10) Broxbourne to Rye House, (11) Rye House to Amwell, and (12) Amwell to Chadwell.

In the present survey of the river it has been found convenient to begin the perambulation at the intake from the River Lee and to give an account of the course of the river from that point to London. In the description which follows the left bank is spoken of as the "lower bank" and the right as the "upper bank." The distances which are given are approximate. They are not the result of accurate measurement, but in each case the distance was judged by observation and the result corrected by reference to the ordnance map. but the figures are always given in round numbers. The maps are taken from the latest ordnance maps, but in all cases corrections have been made in places in wnich changes have taken place since the ordnance survey was made.

Intake from the River Lee (see Map 1).—The water of the New River is taken from the Lee at a point between Hertford and Ware. The present gauge-house is situated quite close to the river and divided from it only by a towing-path. The arrangements which were formerly in use for gauging the quantity of water taken still exist in a building called the balance-house, which is situated a few yards off The arrangement of the intake differs from that of the intakes of all the other metropolitan water companies, and it is the only one which is planned to give accurate results as to the quantity of water taken. The arrangement is simply a floating gauge. The principle on which it works ensures that the size of the inlet through which the water flows is constant, and the gauge is arranged to rise and fall according to the height of the river. The first arrangement of this sort was put up in the balance house. Although it is now no longer used it may be best to describe it first, as it is the simplest, if not the most ancient, form of floating gauge, and is not without historical interest. The house which contains it was built in 1732, when Mill was engineer to the company, and it was re-built in 1770, when Mill and Milne were the engineers. A boat floated up and down according to the height of the water. This boat was suspended from one end of a large oak beam, at the other end of which there was a sluice-gate. The sluice-gate, therefore, necessarily rose and fell according to the rising or falling of the boat. The size of the opening through which the water flowed being constant and the height with reference to the water being also constant it followed that the amount of water which flowed through was constant also. The intake at present used is guarded by a floating boom, and the water passes through an iron grating of which the bars are about 1 in. in width and the meshes 3 in. The boom and gratings keep out pieces of wood and other débris. The amount of water taken from the river daily is said to be 22,500,000 gallons. The sides and edges of the intake opening are formed of bronze, and the sluice-gate through which the water flows is carried by a cross head which rests on a pair of iron boats. In consequence of this arrangement the amount of water remains constant, the depth of the intake being always 16 in. and its width 7 ft. 10 in. The height of the river is recorded by a float of which the index is in the sluice-house. When visited on Jan. 5th, 1897, the water of the Lee was brown and turbid. On that day the height of the water in the river was 2¼ in. above the normal level. Except in very rare instances the water is constantly flowing through this inlet from the Lee down into the New River, but there is an arrangement by which it can be shut off if necessary. The conditions which make it necessary to shut off the water are occasional floods, which cause great turbidity of the water. The supply has also to be cut off when it is necessary to do any work in the course of the stream just below the intake. The way in which water can be shut off is as follows:—There are a number of iron plates 20 in. deep and 8 in. wide; each is provided with a steel "ear" which fits on to a circular iron bar 1½ in. in diameter. By this arrangement practically the whole of the water can be shut off. During the winter of 1896-97 this arrangement was used twice for short periods during flood.

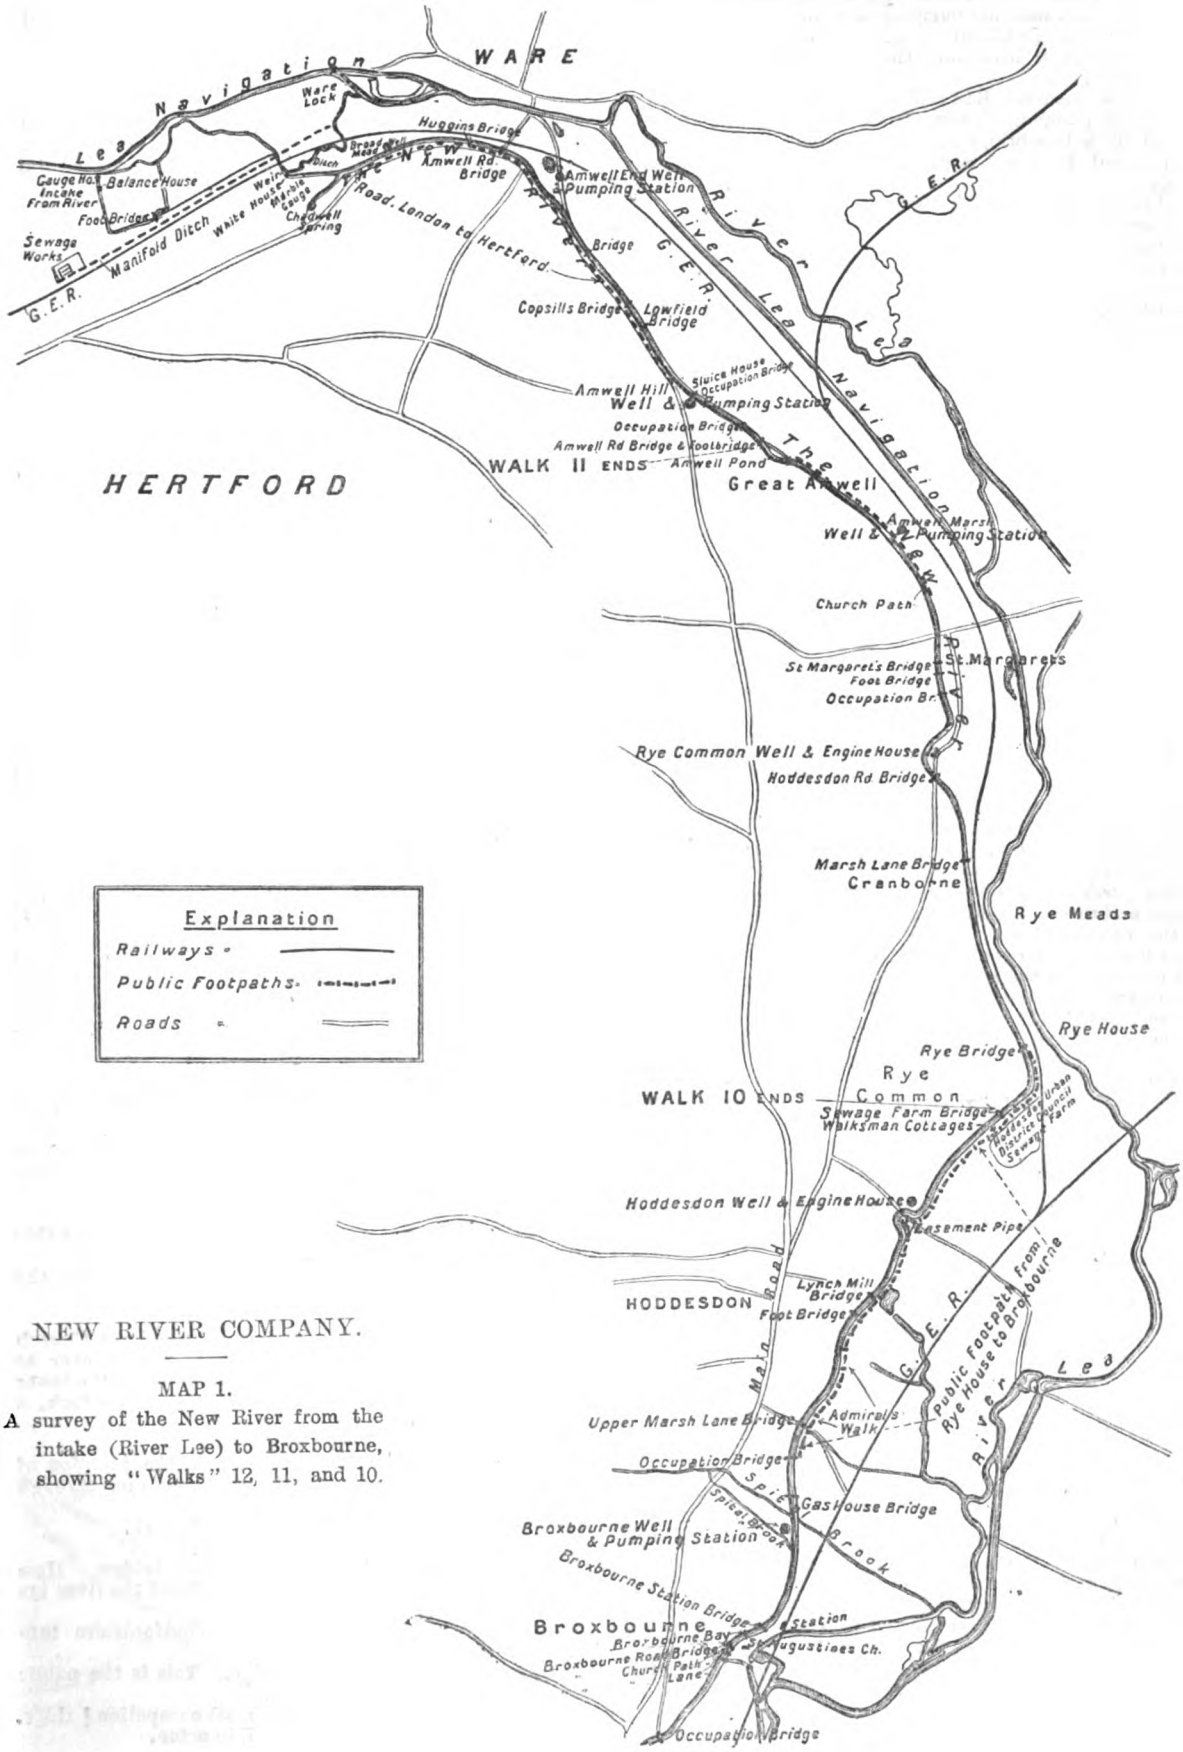
Course of the New River.—From the intake the water is conducted in an open channel which at first passes through open meadows.

50 yards.—Occupation bridge. From this point there is a fence with two bars, 3 ft. in height. The fence is to keep off the cattle from the upper bank.

200 yards.—Here there are the remains of a disused sluice.

270 yards.—Iron bridge. At this point the river is close to the Manifold Ditch.

Manifold Ditch.—This ditch commences at the Hertford Sewage Works and goes into the Lee Navigation Canal at a point below Ware Lock. The length of its course is about a mile and the point at which it discharges into the Lee is about a mile below the intake of the New River Company. For a distance of about half a mile the ditch runs in a direction parallel with the New River and is situated on its upper bank. The ditch has a concrete bottom, the sides forming a segment of a circle. They are lined with bricks laid on edge and set in a concrete bed. The state of the sewage effluent is said to vary considerably. On June 15th it was not particularly offensive. The ditch is conducted under the New River in two 24-in. cast-iron pipes.



250 yards.—Manifold Ditch passes under the New River, and the river then goes under the Hertford branch of the Great Eastern Railway. Up to this point there is a fence on the lower side of the New River; the part between Manifold Ditch and the New River is not fenced. From the point at which the river passes under the railway the fence begins, and it runs on each side of the river for the greater part of the remainder of its course. The standard fence is 2 ft. 6 in. in height and has two wrought-iron rails.

50 yards.—At this point is the White House sluice, which was put up in the year 1746. Here there is a weir. In case of flood the dam boards are removed, and the water flows down a ditch into the River Lee. During the winter of 1896-97 there was one flood during which the dam boards were taken out. The White House contains a spoke and pocket sluice-gate, which is used in flood time to prevent too much water from passing down the course of the river.

50 yards.—At this point a marble gauge is situated; the base of this is formed of marble. As originally planned the water passed through an opening 6 ft. in width and 2 ft. in depth. At the present time there are easement pipes at each side of the gauge, which is no longer used for its original purpose. The easement pipes are 24 in. in diameter. At a distance of 200 yards from this point across the meadow the Chadwell Spring is situated.

Chadwell Spring.—The spring at Chadwell discharges itself into a circular basin or reservoir, of which the depth at the centre is about 18 ft. The reservoir is about 20 yards in diameter, and except at its outlet is surrounded by turfed walks. The amount of water obtained daily is estimated at 4,000,000 gallons, but the quantity varies greatly. It is much diminished after a dry summer. During part of the years 1892-93-94, little water rose for some days. The amount yielded by the spring is gauged twice a week. The water is usually quite clear, but it is occasionally milky. The water from Chadwell Spring joins the branch of the New River which conveys water from the Lee at a distance of 200 yards from the spring. At a point 100 yards further the New River goes close to the road which leads from London to

A survey of the New River from the intake (River Lee) to Broxbourne, showing "Walks" 12, 11, and 10.

Digitized by Google

Hertford. Here there is a bridge leading to Broad Mead, where there is a well and pumping station.

440 yards from Chadwell Spring is Huggins' Shed bridge. Between the New River and Hertford-road there are high spiked railings.

200 yards.—Amwell End bridge. At Amwell End there is a well and pumping station. Near this point the river is crossed by a foot-bridge for a path which leads from the London-road to Ware Station. Near it is Amwell-road bridge.

300 yards.—Red House bridge.

375 yards.—Copsill's bridge.

150 yards —Lowfield bridge.

440 yards.—Amwell Hill. Here there is a well and pumping station

Amwell Sluice.—Near the pumping station there is a sluice house built of wood and having a slated roof. It extends right across the river. There are three bays. The amount of water which passes down the New River is regulated at this point.

200 yards.—Occupation bridge in private grounds.

150 yards —Foot bridge and Amwell-road bridge close together. Here is the junction of walks 12 and 11.

Amwell Pond.—At Amwell was one of the springs from which water was obtained for the New River. There is now no spring in the place at which it formerly existed. There are two islands in the pond which is near to the public highway, and there is here a place at which the public have a right to water horses.

500 yards.—Amwell Marsh. Here there is a well and pumping station. There is a church path from Amwell to St Margarets, the path passing along the lower bank of the New River for about 1000 yards to St. Margarets-road.

150 yards.—Foot-bridge. St. Margarets Bury House is situated here on the upper bank.

100 yards —Foot-bridge, occupation road, St. Margarets Bury.

250 yards.—Occupation bridge, St. Margarets Bury.

350 yards —Rye Common. Here there is a well and pumping station on the lower bank of the river.

50 yards.—Hoddesdon-road bridge.

440 yards —Marsh-lane occupation bridge. Here the river is close to the Great Eastern Railway, Hertford branch.

1000 yards.—Rye bridge road. This is near Rye House station and to the historic house which has given its name to the neighbourhood. From Rye House station on the lower bank of the river a public path leads to Hoddesdon and Broxbourne; the upper bank is fenced in.

400 yards.—Hoddesdon sewage farm bridge. Here is the junction of walks 11 and 10.

The sewage farm is on the lower bank of the river and covers an area of from twelve to fourteen acres. The sewage effluent from Hoddesdon farm goes into the River Lee.

100 yards.—On the lower bank of the river are two walksmen's cottages

600 yards.—Hoddesdon. Here on the upper bank is a well and pumping station. Near the engine-house a 36-in. easement pipe conveys some of the water under the Essex-road and across a meadow into the river, a distance of about 200 yards The course of the easement pipe is shown in the map.

Here is Essex-road bridge.

440 yards —Lynch Mill bridge. The public path, which begins near Rye House, follows the course of the lower bank of the New River to Broxbourne, a distance of about two miles.

100 yards —Foot-bridge to Hoddesdon.

440 yards.—Admiral's Walk. Occupation bridge opposite Yew House, Hoddesdon, which is on the upper bank.

150 yards.—Upper Marsh-lane bridge, Hoddesdon.

200 yards —Occupation bridge, foot-path.

250 yards —Gas House bridge.

300 yards —Broxbourne. Here there is a well and pumping station, situated on the upper bank. At this point a branch of the Spital Brook comes to the upper bank. This brook arises in the woods about two miles away. There is a spring, and the stream also receives surface water. It has not been used for the supply of the New River for twenty years or so. The water now is conducted by a brick channel under the New River, and flows away into the Lee In the old cut, which was formerly used to augment the supply of the New River, a certain amount of water is still kept because by doing so the appearance of the neighbourhood is improved and this is done for the sake of the people who live in the houses near. When the brook is cleared out, which is done yearly, the water collected in this part of the cut is allowed to pass into the river. There is a 6-in cock between the Spital Brook and the river.

500 yards.—Broxbourne Station bridge.

100 yards.—Broxbourne Bay. Here there is a sluice, worked by cogged gear. There is a fall of about 6 in. The fall varies from 3 in. to 1 ft. according to the state of the river. St. Augustine's Church is here on the lower bank of the river.

60 yards.—Broxbourne Bridge.

30 yards.—Broxbourne Church path bridge.

30 yards —Broxbourne Church-lane bridge.

550 yards.—Occupation bridge.

The description of the survey should now be followed on Map 2.

100 yards.—Broxbourne-road bridge. Here is the junction of walks 9 and 10. (See Map 2.)

100 yards.—Bridge, and occupation bridge.

30 yards —Page's-lane bridge.

440 yards —Brickfield-lane bridge and foot path.

350 yards.—White Horse-lane bridge. This bridge has an easement culvert on each side to convey part of the water of the river. It is therefore called a "three-way bridge." From this bridge to Wormley foot-bridge there is a public foot-path on the upper bank of the river.

300 yards.—Manor Farm (Wormley) occupation bridge.

30 yards.—Wormley foot bridge. Here the public foot-path crosses the river.

880 yards.—Ground water is conducted under the New River from the right to the left There is an aqueduct over Watery-lane, Turnford. Here there was formerly a wooden trough. About 300 yards above this point was the Turnford loop of the New River, which has since been replaced by a straight cut The site of the Turnford loop is given in the map (Map 2).

400 yards.—Turnford. Here there is a well and pumping station on the lower bank. From Turnford Station to Cheshunt there is a public foot path on the lower bank of the river.

600 yards.—Brookfield occupation bridge

Cheshunt.—Here there is a disused well and two ponds having areas of 8 and 13 acres respectively, formerly used as reservoirs This water is not now used for the supply of the New River, and the flood water which collects in the ponds is conducted under the river in a culvert and flows away to the Lee. At Cheshunt there are two cottages, one occupied by a walksman, the other by a "gratesman"—a labourer employed to keep the grate in working order, and who is held responsible for its efficiency. Here is Brookfield-lane bridge. From this point to Clark's-lane bridge there is a public foot-path on the lower bank.

440 yards.—Clark's-lane foot-bridge.

Just beyond this point is Kilsmore Island. It is near the upper bank of the river.

150 yards.—Church-lane bridge, Cheshunt. One gas main here crosses the river. On the upper bank there is a market garden.

300 yards —Church-path bridge.

200 yards.—Pest House bridge. On the upper bank at this point are situated a nursery and Cheshunt College.

600 yards —College-road bridge. Here is a tank for the supply of unfiltered water for the Cheshunt roads.

150 yards —Grove House private foot bridge.

300 yards.—At this point a path from Cheshunt Church comes to the upper bank of the river, crosses over at Theobald's Park foot-bridge, and then passes along the lower bank of the river to the south end of Theobald's Park, a total distance of about a mile and a half.

880 yards —Theobald's Park foot-bridge.

200 yards — Theobald's-lane. Here is the junction of walks 7 and 8. From this point the river runs through Theobald's Park.

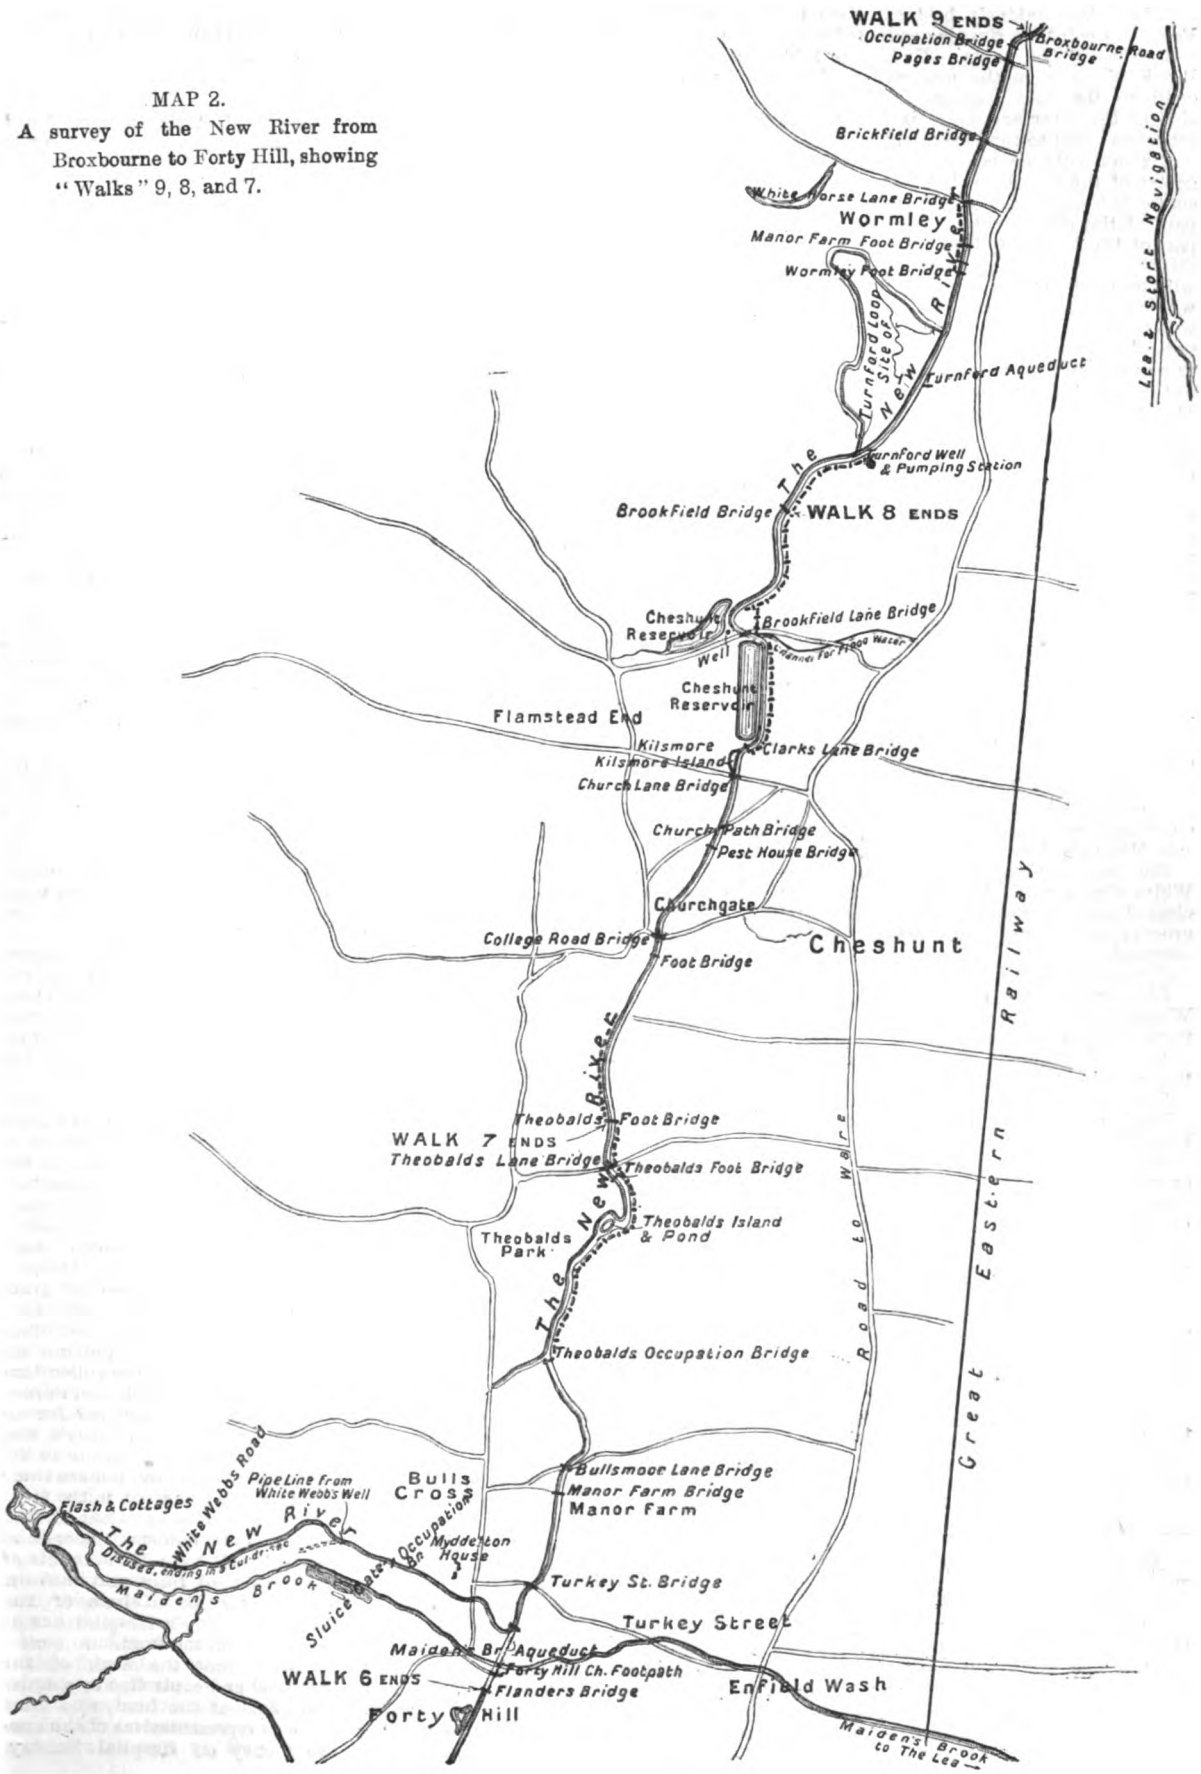
30 yards —Occupation bridge, Theobald's Park.

300 yards —Theobald's Pond and Island.

700 yards —Theobald's Park occupation bridge. Here the foot-path crosses the river. Both banks of the river are private from this point.

100 yards.—New River passes from Hertfordshire into Middlesex.

440 yards. — Bullsmore-lane bridge. This is the public road from Bull's Cross to Waltham.



150 yards.—Manor Farm (Bull's Cross) occupation bridge.

440 yards.—Turkey-street bridge, Edmonton.

MAP 2.

A survey of the New River from Broxbourne to Forty Hill, showing "Walks" 9, 8, and 7.

Digitized by Google

300 yards.—Maiden's bridge. Here there is a grating. From this point the river is conducted in two 48-in. pipes for a distance of 350 yards. Under the bridge passes Cuffley Brook, which is in the map called Maiden's Brook. This conducts the land drainage from the country on the west side of the river and takes it into the River Lee crossing from the upper to the lower bank.

A short distance below Turkey-street bridge the original course of the New River has been altered. The water is now conducted across the valley in an aqueduct. The disused part of the river went in a nearly westerly direction, and part of this has lately been restored and the banks have been raised. The part of the river which has lately been repaired will be used for the conveyance of water from a new well which has been dug at White Webbs. The water from this well is to be conveyed in a pipe which will open into this part of the river, and the water will flow in an open course in a direction exactly opposite to that which was taken by the water when this part was used for its conveyance to London before the aqueduct was made. The description which here follows of this part of the New River will be best understood by the study of the accompanying map (Map 2). The water from White Webbs will go into the open course channel of the river at the place marked with an arrow, and from this point the water will flow in an easterly direction and join the New River just before it passes into the aqueduct over Maiden's bridge. The part to the west of the point at which a pipe will enter the river from White Webbs will still be disused. The old course of the river can be easily traced up to Flash-lane Cottage.

The following is a brief description of the course from Maiden's bridge aqueduct to Flash-lane.

300 yards.—Road from Enfield to Cheshunt.

200 yards.—Occupation bridge in the grounds of Myddelton House. A few years ago the water in this part of the river was stagnant. The banks of this part have been raised and turfed over. The banks have been raised to the extent of about 1 ft. to 2 ft. for a distance of about one-third of a mile.

300 yards.—Wooden occupation bridge. Here there is a sluice gate which can be used for allowing the water to pass into Maiden's Brook.

200 yards.—From this point goes the line of pipes to White Webbs well. From this point the river has not been cleared out nor have the banks been raised. Weeds are growing in it. On June 16th the water was clear, but it was stagnant.

880 yards.—White Webbs Road.

200 yards.—Here, near the bank, is the 18-in. pipe from White Webbs. The pipe from the well has already been laid from this point to the well.

440 yards.—Enfield Flash bridge. Here there is an overflow weir to Maiden's Brook.

200 yards.—Above this is Flash foot-bridge. Here the "loop" of the New River ends—i.e., in a *cul-de-sac*. The last 200 yards are next Flash-lane.

The return part of the loop has been filled up and the ground it occupied has been taken by adjoining landowners.

From this necessary digression we return to the new course of the river.

Maiden's Bridge.—There is an aqueduct over Cuffley or Maiden's Brook. It is about 25 yards in length, and the water from the river is conducted in two 48-in. pipes, which are visible in the aqueduct house, which is covered with corrugated iron, and has a walk between the pipes. The pipes are about 20 ft. above the level of the bed of the Cuffley brook.

50 yards.—Forty Hill Church foot-path.

250 yards.—Pipes open into the river again. There are three pipes which open into the river.

The survey will be continued with similar detail and illustration.

(To be continued.)

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting of this association will be held at 11, Chandos-street, London, W., on Wednesday, Nov. 17th, under the presidency of Dr. T. W. McDowall. The Parliamentary Committee will meet at 11.30 A.M. and the Handbook Committee at 12 noon. The council meeting will meet at 2 P.M., and the general meeting will be at 4 P.M., when new members will be elected and papers read. The members will dine together after the meeting at the Café Royal, Regent-street, at 6.30 P.M.

MEETING OF THE HOSPITALS ASSOCIATION.

A LARGELY attended meeting of this Association was held in the board room at Charing-cross Hospital on Oct. 28th to hear from Sir Sydney Waterlow, chairman of the Distribution Committee of the Hospital Sunday Fund, an account of the methods pursued by the Distribution Committee of the fund to which he belonged in making their awards to the various hospitals, and from Mr. R. B. D. Acland, chairman of the Hospital Saturday Fund, an explanation of the method of distribution adopted by his fund.

Mr. H. COSMO O. BONSOR, M.P. (President of the Hospitals Association), acted as chairman.

Sir SYDNEY WATERLOW, Bart., then read the following paper:—

"Several of the friends and warmest supporters of the Hospital Sunday Fund have asked me to attend here to-night to explain to them, and through them to the public generally, the system upon which the money collected on Hospital Sunday is divided between the hospitals, dispensaries, convalescent homes, and other institutions applying for an award. Collections for the benefit of the Fund have now been made for twenty-five years successively, and the total sum collected to July 30th, 1897, was £913,489. It is not surprising that the friends of the movement and the public generally should be desirous of understanding the manner in which this large sum has been divided among the numerous institutions applying for a share of the funds. This desire has been no doubt further stimulated by the fact that probably half a million of money will be raised this year by the Prince of Wales's Hospital Fund for London. When in February last His Royal Highness made his appeal for contributions to this Fund he stated: 'I am aware that the task of distributing the funds when collected will not be without its difficulties. It may be desirable in the future to seek the assistance of representatives chosen by the hospitals, but for the first year we shall rely upon the coöperation of the Distribution Committee of the Hospital Sunday Fund.'

"The Distribution Committee consists of the Lord Mayor, as President, and ten members chosen annually by the Council; some of the members have served upon the Committee for more than twenty years. The Fund was started at the Mansion House in the year 1873. I was the first President and treasurer, and have been chairman of the Distribution Committee from the commencement. I have rarely missed attendance at any of the meetings, and consequently am perhaps more responsible than any other person for the preparation of the laws by which the distribution of the money is governed, and for the interpretation which has been given to those laws from time to time. All the members of the Committee have necessarily gained considerable experience in dealing with the important duties cast upon them. We have upon the Committee a very eminent surgeon, and a physician of high standing in the city of London; the professional knowledge of these two gentlemen has been of great assistance to the Committee. It has also been thought right not to elect upon the Committee any gentleman who held office in connexion with any one of the hospitals applying for a share of the money. For some years after the collections were commenced, none of the three endowed hospitals—St. Bartholomew's, St. Thomas's, or Guy's—applied for or received any award. The first application from Guy's was in the year 1888. No award has hitherto been made to St. Thomas's, as the governors of that hospital did not see their way to deliver copies of their accounts made out in the form prescribed by the hospital authorities and the Council, and certified by a public accountant. It is, however, understood that the treasurer of St. Thomas's will have the accounts of his hospital prepared in the prescribed form, and that an application will be made next year for a share of the Hospital Sunday Fund. St. Bartholomew's Hospital has at present no need for any assistance from the fund.

"It should be borne in mind that the work of the Distribution Committee is governed and controlled by a series of laws passed by the constituents of the fund, who meet annually at the Mansion House as representatives of the congregations contributing the money on Hospital Sunday.

Digitized by Google

These laws direct that only those hospitals and dispensaries which are managed by committees duly constituted, shall be allowed to participate in the fund. The awards to hospitals, &c., shall be primarily based on the average total expenditure of each institution for the last three years after deducting therefrom (1) a sum equal to the income derived from endowments and realised property; (2) the amount received in legacies exceeding £100 each, unless such legacies have been necessarily spent to meet the current expenditure of the institution; and (3) the expenses of management.

"In every case the merits and pecuniary needs of the institution concerned shall be fully inquired into and considered by the Distribution Committee, and the award made shall be determined in accordance with the judgment of that Committee upon such merits and needs, provided that in no case shall the grant be reduced below the arithmetical basis, or withheld, until a conference shall have been sought with the managing committee of the hospital affected. The payments made by or on behalf of patients shall be dealt with, in each case, as the Committee of Distribution may see fit. This was found necessary owing to the very great variation in the amounts and in the circumstances under which patients' payments are made. No institution, to the benefits of which admission can only be gained by election from the general body of subscribers, shall be eligible for grants from the fund. The Committee shall have power to set aside 5 per cent. of the total amount of collections for the purpose of surgical appliances. There are several other minor provisions, but they have no material effect on the amount awarded. A careful consideration of these laws clearly indicates that the Distribution Committee are to recommend awards to each hospital, &c., in accordance with its needs and merits, subject to the definite directions for arriving at these important factors. Every institution desirous of applying for an award has to send to the secretary of the Fund, not later than February or March in each year, an application to participate. This must be accompanied by a correct copy of the printed report, and of the receipts and expenditure of the institution, made out upon the prescribed form agreed upon between the council of the Fund and the managers of the leading London hospitals. These accounts are then required to be analysed on a form supplied for the purpose in duplicate. As these forms are all alike, the comparison of the relative pecuniary needs is not difficult.

"The expenditure is divided under two heads—maintenance and management. Maintenance includes provisions, surgery, domestic establishment charges, rates and taxes, rent (if any), salaries and wages (except for those persons engaged in the administration), miscellaneous expenses, with a separate item for extraordinary repairs and new buildings, which is always separately considered. The administration or management includes official salaries and commissions, official printing, postage, telegrams, &c., official advertisements, law charges, incidental management expenses, with a separate item for appeals and festival expenses, separately dealt with. It will be seen that maintenance, in other words, includes all the money spent in the care and cure of patients, while the administration is the cost of the office management controlling the work. The festival expenses I will hereafter refer to. The income is divided under two items—charitable revenue and proprietary revenue. The charitable revenue includes subscriptions, donations, the Sunday and Saturday funds, church collections (if any), festivals, legacies under £100, or exceeding that sum, if absorbed in current expenditure. The proprietary revenue, or secured income, includes interest on legacies exceeding £100 (when not required for current expenditure), dividends, interests, rents, &c., from invested property, fees paid by nurses, and patients' payments.

"In order to arrive approximately at the needs of the hospital, the average of the moneys spent in maintenance and management in each of the three past years is carefully calculated. From the total expenditure in each year we then deduct the proprietary or secured annual income. The money expended on the average of three years in the treatment and support of the patients, less the proprietary revenue and the expenses of management, is regarded as the financial needs of the hospital, which have to be provided from year to year from the public and from uncertain sources. This is called the basis of the award, and is raised or lowered at the discretion of the Committee as soon as they have determined the merits of the particular institution. The task of arriving at the merits is no doubt more difficult than determining the financial needs and rests to a greater extent on the discretion of the Committee. Detailed information, including the number of beds, the average number occupied daily during the last year, the average number of days each in-patient was resident, the average cost of each in-patient per week, and the average cost of each out-patient, as far as this can be calculated, is given for the past year; the average number of in-, out-, and lying-in patients, both counting renewals and without renewals; and also the total number of attendances for the past three years is all laid before the Committee.

"Although the figures thus furnished in no way enter into the arithmetical calculation of the needs of the hospital they have to be most carefully considered when determining the merits; the average cost of each in- and out-patient and the numbers of beds occupied, as compared with those unoccupied, varies so very much in different hospitals. Let me take eight of the large general hospitals, viz., Charing-cross, Guy's, King's College, London, St. Mary's, Middlesex, University, and Westminster, the management in which may be regarded as satisfactory. The cost of each in-patient per week varies from 26*s.* to 36*s.*, while in smaller hospitals and special hospitals it reaches as much as £2 8*s.* In determining whether the amount is or is not excessive, the Committee have naturally to bear in mind the nature of the work carried on—the character of the diseases dealt with, especially in special hospitals, as some classes of patients, if efficiently treated, cost much more than others. The percentage which the money spent on administration bears to the money spent on maintenance is necessarily a very important factor in determining the relative merits of different hospitals. Taking the eight hospitals previously referred to, the percentage of management to maintenance varies from 3·883 per cent. to 13 per cent. This may be to some extent accounted for by slight variations in the manner in which the accounts are stated, but not materially. In the special and smaller hospitals the percentage varies from 2 per cent. to 31 per cent. It must, however, be borne in mind that in smaller hospitals the expenses of management are unavoidably much larger than in the larger hospitals; but there can be no doubt that money contributed to the large, well-conducted hospitals, goes very much farther, and secures the efficient treatment of a larger number of patients than in the smaller hospitals. The Committee have, however, always considered that when comparatively small hospitals are erected in outlying districts at some distance from existing hospitals they ought, if well managed, to have every encouragement. A lithographed abstract analysis of the accounts of each hospital is given to every member of the Committee, attention is called to the particulars I have referred to—no decision is recorded until these points have all been discussed, a vote is then taken in each case.

"It should always be borne in mind that whenever the Committee are of opinion that the information before them does not seem to justify them in recommending an award equal to the natural basis disclosed by the figures, they are required by Rule 5 of the laws of the Constitution to ask for a conference with the managers of the hospital affected. During the present year conferences were invited with the managers of thirty-eight institutions, and in thirty cases deputations were interviewed. In several of these cases the basis was materially reduced, the managers promising that the defects complained of should be remedied in the future, and in two cases the management was so bad that no award was recommended. The item, cost of appeals and festival expenses, is one which gives the Committee much trouble, as it cannot be dealt with upon any hard and fast line. Speaking, however, for myself, I have always held that where these expenses result in bringing into the treasury of the hospital only 50 or 60 per cent. of the sum contributed by the persons present at the festivals they ought not to be encouraged.

"I have endeavoured to make the method adopted by the Distribution Committee as clear as possible. I will now give two illustrations or examples with the view of rendering my statement more intelligible.

"*London Hospital.*—The average total expenditure for 1894, 1895, and 1896, after deducting each year the proprietary revenue, was £44,884. From this sum we deduct the average cost of management for the same years—viz., £2277, leaving £42,607 as the needs of the hospital to be collected annually from the outside. This forms the

Digitized by Google

primary basis, to be raised or lowered on the merits, at the discretion of the Committee.

"*St. George's Hospital.*—The average total expenditure for 1894, 1895, and 1896, after deducting each year the proprietary revenue was £18,441. From this sum we deduct the average cost of management (£1481), leaving £16,960 as the needs of the hospital to be collected annually from the outside. This forms the primary basis, to be raised or lowered at the discretion of the Committee.

"The question as to the continually increasing number of out-patients at our large hospitals has been much discussed of late, and these discussions have disclosed a great diversity of opinion, but as I have previously stated the number of out-patients treated at each hospital has hitherto been regarded by the Distribution Committee simply as evidence of the amount of work done in treating the sick poor, and has not been an important factor in determining the amount of the awards to each hospital, I have therefore refrained from dealing with it here.

"The system we are discussing may be very shortly summarised thus: By means of the analyses of the accounts to which I have referred, the Committee are enabled to arrive at the sum of money spent by each hospital on the average of the past three years in the treatment and support of the patients. Deduct from this the proprietary revenue, or ensured income, and you have the figures representing the needs of each hospital. These figures form the primary bases of the awards. The merits are then discussed on reference to the accounts, and from information placed at the disposal of the Committee from various sources. If there is no fault to find with the management, the figures forming the bases are confirmed or raised; if the management is unsatisfactory, a conference is invited with the managers. The money available for distribution is then divided in accordance with the figures of the bases. It has varied during the last twenty-five years from 1*s.* 10*d.* to 2*s.* 2*d.* on each basis, or approximately, on each £ needed for the support of all the hospitals, &c. The variation is governed by the amount collected each year. It should also be remembered that the money is distributed within a few weeks after it has been collected. I have always felt that those who give the money intend it for the relief of the sick poor in the year in which it is contributed.

"I think I am justified in saying that this system of distribution has been thoroughly successful and satisfactory to the public. The awards have for the last twenty-five years been submitted for the approval of the Council, consisting of 100 members, at a meeting in the Mansion House, and published in the London press. On one occasion only has any alteration in the awards recommended by the Committee ever been thought necessary and made. If we take the average for the last twenty-five years of the contribution to the hospitals from the Sunday Fund at 2*s.* in the £ of the needs of each institution applying it will be seen that the Fund provides only one-tenth of the cost of the treatment and support of the sick, leaving the other nine-tenths to be provided by subscriptions, donations, &c., from the public and from legacies or other sources.

"But this is not by any means the only benefit which the hospitals and the public have derived by the action of the Committee of Distribution. With the assistance and full concurrence of the secretaries and officials of the hospitals all the accounts of income and expenditure are now prepared on one uniform plan and certified by a public accountant before they are subjected to the detailed criticism of the Committee. This arrangement has undoubtedly in many cases ensured much greater economy and an improved management of the hospital funds. Again, my experiences of the last twenty-five years has much strengthened my early conviction that an annual sermon in the churches and chapels followed by a collection was the best, and likely to be the most permanent, method of raising money for hospitals, for it is well that on one Sunday in each year all the ministers and the whole population in the churches and chapels should forget for the moment their denominational differences and join hearts in one Christian duty upon which all are agreed—viz., the duty of relieving the sick poor, each one as far as he is able; and I feel sure that a large number of those who contribute small sums at the collection on Hospital Sunday are so impressed with the sermons that they give large donations at a later period or leave legacies for hospital purposes.

"In conclusion I wish it to be distinctly understood that I alone am responsible for the opinions expressed in this paper. It has never been read to my colleagues on the Committee, and therefore I have no authority to speak except for myself."

Mr. R. B. D. ACLAND, chairman of the Hospital Saturday Fund, in opening the discussion said it afforded him great pleasure to address the meeting on the system of distribution adopted by the Hospital Saturday Fund, for it was only by criticism based upon full knowledge of the facts that any advance could be made. A meeting of this sort should have but one result, namely, that the Metropolitan Hospital Sunday Fund, the Hospital Saturday Fund, and now the Prince of Wales's Fund should distribute their money on the same systems. That had long been his ideal and he looked upon this meeting as the greatest step to progress in that direction since the inauguration of the Fund. He wished to call attention to the difficulties which must confront any distribution committee. The first was the extreme difficulty of getting accurate returns of the number of patients from the different hospitals, and he was perfectly certain that anyone who had served on a distribution committee could bear him out in that statement. The second difficulty was peculiar to the Hospital Saturday Fund which was a working man's organisation. For the past twenty-three years the Hospital Saturday Fund had been trying to work out its own salvation in the way of collecting funds. It had received no assistance whatever from people with a particular knowledge of hospital work, and if there were defects in the system it was due to the fact that they had to work it out from paper rather than from an actual knowledge of the inside work of hospitals. Sir Sydney Waterlow's system might be summed up thus. Given the arithmetrical basis it was left to the Distribution Committee to say whether the grant should be made on that basis or not. It might be a very excellent plan where, as in the case of the Hospital Sunday Fund, the committee was composed of men who possessed the fullest knowledge of hospital administration, but it would prove a very bad system in the case of the Hospital Saturday Fund, where no one on the committee possessed such special knowledge. The first thing to be decided was what were the institutions to which awards should be made. They had found from time to time that institutions had applied for grants which were neither hospitals nor dispensaries, and therefore they had thought it necessary to frame a definition restricting grants to such institutions as treated the sick poor only, including convalescent homes and nursing institutions. The latter, he understood, did not participate in the Hospital Sunday Fund distribution. They had had to make this definition so as to exclude medical missions, the Salvation Army, &c. The next thing was to arrive at the amount to be distributed. Certain percentages were first deducted for what he might call the outside working of the Hospital Saturday Fund, which was not a mere collecting and distributing body. It did a great deal of other useful work in connexion with ambulance and first aid, the supplying of necessaries for such work, the supplying of surgical instruments, and the granting of loans to people who wished to obtain the benefits of convalescent homes, but who could not afford to pay ready money. From the total amount collected after payment of expenses 6 per cent. was deducted for surgical appliance work, and 8 per cent. for the purchase of letters of recommendation. A sum not exceeding 1 per cent. was also deducted for the Morley Convalescent Home, which was the outcome of the Hospital Saturday Fund, and they quite naturally desired to give in some way additional support to their own child. Then special grants might be made for certain dispensaries, ambulance work, &c. All that practically came to about 13 or 14 per cent. of the whole collection. The balance was divided amongst hospitals, convalescent homes, and different dispensaries. The basis of award except in one particular resembled very much that of the Metropolitan Hospital Sunday Fund. It was based upon the relief afforded, economy practised, and efficiency shown. They attempted to arrive at the efficiency of the hospitals as far as they could discover it by a series of questions asked with a view to show the probability of the hospitals being properly managed. As an example of the questions he instanced the following: Have you a committee of management? How is it elected? Is there an independent finance committee? By whom elected? Is there an annual meeting of the governors and subscribers? If so, give date and where held, and state whether reporters are admitted? Questions of that sort gave outsiders certain knowledge of the hospital being properly managed. Is there

Digitized by Google

efficient control? If so, are the people properly elected to give reasonable guarantee for such control being exercised? Are you willing to give to the Hospital Saturday Fund in return for grants letters in the same proportion as you give to ordinary subscribers? May patients be visited on Sundays, and if so, at what hours? That represented the view of the working man, and it seemed a reasonable one. He (the working man) thought that a guinea subscribed by himself and his shopmates was likely to be as valuable as the rich man's guinea. The use made of the questions was this. A total number of marks of fifteen were given for efficiency. Each question which was answered adversely or which showed that the hospital was not likely to be well managed would cause the hospital to lose a mark. Provisions were also made to try to secure that the small hospital should not get too large a proportion of the funds as compared with the larger institutions. Then with regard to economy, the Metropolitan Hospital Sunday Fund practically left the matter to the Committee of Distribution. The Hospital Saturday Fund tried to work out a series of rules which had the effect of comparing fairly the economy shown between the different hospitals. The system was based upon the cost per bed in the institution and the cost per out-patient as shown by the returns. The cost of a bed varied according to the kind of work which was efficiently done in the hospital. It would not be fair to compare a general hospital with a hospital like Brompton, and so they had tried to group the hospitals in classes and work out averages for the cost per bed and out-patient for each one of the classes. The classes were five in number—namely: (1) general and ophthalmic hospitals; (2) hospitals for diseases of the throat, cancer, chest, epilepsy, fistula, skin, and for diseases of women; (3) children and dental; (4) lock hospitals and orthopædic; and (5) lying-in. The cost per bed was again divided into four classes. If the cost of a bed is £60 no mark is lost at all, but if the cost is £90 four marks are lost. In regard to the cost of management, where it was 10 per cent. one mark was lost; 13 per cent., two marks; 16 per cent., three marks; 19 per cent., four marks; 22 per cent., five marks; and above 22 per cent., six marks; so that it was quite possible under this system that hospitals extremely expensively managed would get no marks at all for economy. The amount distributed was divided so as to bring in these considerations of relief, economy, and efficiency. Of the total amount to be distributed five-sixths was given for relief and efficiency and one-sixth for economy. As regarded relief, the difference between the Hospital Sunday and Saturday Funds, he thought, was smaller than appeared at first sight, for by deducting the proprietary revenue some account must be taken of the work which was done. The Hospital Saturday Fund did it much more directly. They took the number of patients actually treated and a certain number of marks were given, for it was obviously necessary in a proper system that some consideration should be given to the income which was in the possession already of the institution, otherwise a hospital like St. Bartholomew's would get a larger grant than the poorest hospital in the whole of London. For the purpose of relief marks, only those who did not pay for themselves or were paid for out of the proprietary revenue of the hospital were counted. There were certain hospitals in London which were really paying institutions, and a rule had been made that a hospital which received 75 per cent. or upwards of the cost of maintenance from patients should not receive any award. If any of the subscribers to the Funds desired the benefits of such institutions the Fund bought letters for them. Then with regard to the relief marks for in-patients they had been seeking how it would be possible to help hospitals who closed their wards for fear of running into debt by asking for a return of the daily average of beds occupied and the number of beds in the hospital which could be occupied if funds permitted. One mark was given for every two beds not occupied. In the out-patient department marks were awarded according to the number of patients treated. Roughly speaking, one mark was given for every 2000 to 800 patients. It would be clear that at some special hospitals the average number of individual attendances of out-patients would be greater than at a general hospital, and in such cases proportionate amounts were granted.

The Rev. C. H. GRUNDY thought that overlapping of philanthropic movements was one of the curses of the age. He would like to see the two funds amalgamated.

Sir HENRY BURDETT pleaded for full discussion and criticism from the large number of representatives of hospitals who he knew were present. He did not know how Mr. Acland could justify the system, which as he (Sir H. Burdett) understood it worked out in this way. You took off marks for inefficiency up to a maximum of 23 per cent. for management, which entailed a loss of six marks. After that the charity might spend on management 11½*d.* out of every shilling they received from the public, but they would only lose six marks. Before disposing of one single penny to the hospitals 8 per cent. was taken off for letters. He did not see any justification for this. Since Mr. Acland had become chairman of the Hospital Saturday Fund he had devoted a great deal of time to it, and he (Sir H. Burdett) was quite clear that whatever was thought of his system of distribution everyone would be unanimous upon one point, and that was that much that was good in the Hospital Saturday Fund was largely due to the attention to duty which had characterised Mr. Acland's tenure of office.

Canon GRAHAM thought the system adopted by the Mansion House Fund was superior to that of the Hospital Saturday Fund.

Lord STAMFORD said it had been stated and denied that the number of out-patients counted in the allocation of grants. He understood that Sir Sydney Waterlow would say that a small amount of weight would be given to the number of out-patient attendances, and he gathered that Mr. Acland would allow that more weight was given by the Hospital Saturday Fund to these attendances. He thought the public would be much interested in hearing what amount of weight was given by the Funds to this point.

Mr. COHEN asked what was the relative cost per cent. of the distribution of the two Funds. (Mr. CUSTANCE, the secretary of the Metropolitan Hospital Sunday Fund, here interposed with "distribution and collection," which caused the speaker to amend his question.)

The Rev. Prebendary KITTO pointed out that the two Funds approached the matter of distribution from two different points of view. The Hospital Saturday Fund was looked upon as a system of assurance and the Hospital Sunday Fund as a system of charity. Amalgamation he thought absolutely impossible.

Mr. RYAN (St. Mary's Hospital) said that the system adopted by the Hospital Saturday Fund was one which a skilled man would learn to apply in an exceedingly short time. Once the basis was settled it was no more difficult than that adopted by the Metropolitan Hospital Sunday Fund. But a good many objections could be taken to the constituent parts of the system when it was examined point by point. To take an example. Where a bed cost £60 the full number of marks for economy was given; when £70 was reached one mark was taken off, and so on. Now it was clear to him that it did not in the slightest degree follow that the institution whose cost per bed was the cheapest was the most economical. With regard to the working-man's guinea being worth as much as the rich man's guinea, he pointed out that a gentleman who gave a donation of thirty guineas was entitled to three in-patients' letters and a certain number for out-patients. Everyone knew that £30 did not provide for one patient, let alone three, but the greater part of the letters were never used.

Mr. THIES (Royal Free Hospital) suggested that a committee consisting of the secretaries of hospitals might be allowed to examine the two systems of distribution. He thought it most desirable that the two Funds should make themselves more in touch with the institutions by appointing small committees to visit the hospitals.

The Rev. N. BROMLEY (King's College Hospital) said that large general hospitals only received from the Hospital Saturday Fund about a quarter of the sum granted by the Hospital Sunday Fund.

The CHAIRMAN, in closing the discussion, said there was not the slightest doubt that both Funds had done their best and in an impartial way.

Mr. ACLAND, in replying, pointed out the extreme difficulty of getting at the facts with regard to the working of hospitals and especially with regard to the number of patients who attended the hospitals. With regard to the objection that certain deductions were made before any sum was distributed there were certain expenses in training men in ambulance work and supplying the necessary apparatus. Surgical appliances were also supplied. This was also done by the Metropolitan Hospital Sunday Fund and he did not see why the Hospital Saturday Fund should not do the same. He had come to the conclusion that £60 per bed was too low and the figure would be altered. The probable explanation of that amount being taken was that

Digitized by Google

some hospital had sent in that estimate. That, again, illustrated the fact that a number of men were trying to distribute without full knowledge of the facts. He hailed with delight the suggestion with regard to a meeting of hospital secretaries. The members of the Fund did their best to visit hospitals, but they were all working men and for the most part had to do their visiting between seven and ten in the evening. A speaker had said that you could not judge of economy by taking the cost per bed and out-patient. Would he suggest a better plan? Referring to the question of the worth of the working man's guinea, he said that about 22,000 letters were issued a year, and of that number perhaps 90 per cent. were used. In return for these they distributed a sum of money which worked out at about 15s. each for all the letters distributed. Speaking with reference to the way in which the merits of an institution were arrived at he quoted from Sir Sydney Waterlow's paper, and remarked that while he (Mr. Acland) had explained how it was done Sir Sydney Waterlow had not. With regard to the cost of distribution and collection he could not deal with the relative cost. The cost of the office expenditure of the Metropolitan Hospital Sunday Fund was some 8 per cent. less than the cost of the office expenditure of the Hospital Saturday Fund. The total amount of the expenditure of the Hospital Saturday Fund included every single penny down to a postage stamp. In the case of the Hospital Sunday Fund a large amount of work was done gratuitously. The large church collections were not the consequence of a single sermon but of an enormous amount of gratuitous work. The work of the Hospital Saturday Fund could not be done that way. He was quite sure that Mr. Cohen did not wish to pit the two Funds against each other, but he was glad that Mr. Custance's remark had given him an opportunity of delivering himself in regard to this matter. Some five or six thousand collections were made for the Hospital Saturday Fund every week. With regard to out-patients, taking Charing Cross Hospital as an example, he said there were 21,000 out-patients last year, and one mark was given for every two thousand. With reference to the loss of marks above 23 per cent. in relation to management there were provisions which prevented unfairness. With regard to 8 per cent. being set aside for letters other funds were not blameless in this respect.

Sir SYDNEY WATERLOW said the cost of collecting and distributing the Hospital Sunday Fund was about 3¼ per cent. He quite agreed that it would be difficult to amalgamate the two Funds, but it did not follow that the two Funds could not be distributed upon the same plan. No one would rejoice more than he to have some kind of conference with reference to that matter. He had no faith in the figures supplied with regard to the out-patient departments, for, as had been pointed out, many patients went to a hospital on from five to eight occasions in a year. He believed the hospitals gave the best information they could. With regard to the question of merit as judged by the Hospital Sunday Fund, which had been described by one speaker as "slap-dash," he said there were men on the committee with a large experience of hospital business. He hoped that the use of letters would be dispensed with. He hoped to see the day when people would be admitted and treated free. It was the letters given to subscribers that really made the most serious abuse of the out-patient department. If the two Funds could meet that question might be discussed with some advantage to both. If the secretaries of hospitals could meet together any recommendation they might make would be listened to with attention and respect.

Votes of thanks to Sir Sydney Waterlow, Mr. Acland, the chairman, and the officers of Charing-cross Hospital for the use of the board room terminated the proceedings.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—At a general meeting of this association, held on Oct. 29th, in the Queen's Hotel, Manchester, Dr. E. Rayner in the chair, Mr. R. B. Anderson delivered an address on Medical Defence, illustrating the subject by a narration of his own case, a full account of which has already been given in our columns. A motion of thanks to Mr. Anderson for his address, which was unanimously adopted, contained a resolution that the questions of the advisability of supporting Mr. Anderson's appeal to the House of Lords should be referred to the committee of the association "for the consideration of what practical measures could be taken to carry the issues involved to a satisfactory result."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE quarterly Comitia of the Fellows of the Royal College of Physicians of London was held on Oct. 28th, the President, Sir SAMUEL WILKS, Bart., being in the chair.

There were admitted to the Membership of the College: W. C. Bosanquet, M.A., M.B. Oxon., M. G. Foster, M.A., M.D. Camb., F. J. Poynton, M.D. Lond., H. R. Smith, M.D. Lond., J. P. Stewart, M.A., M.D. Edin., and W. H. B. Stoddart, M.B. Lond.

Licences were granted to 116 candidates who had passed the recent examination (34 being under the new regulations).

A communication was read from the Foreign Office forwarding a medical report and poisoned arrows from Uganda, and requesting an examination of the poison. On the motion of the Senior Censor, seconded by the Registrar, the specimens were directed to be sent to Dr. Woodhead for examination and report.

Communications were read from Mr. Trimmer, reporting the proceedings of the Council of the Royal College of Surgeons of England on July 29th and Oct. 14th.

A request by Mr. W. J. Harvey for permission to consult the Harvey manuscripts in the possession of the College was referred to the Library Committee, and an application from Dr. G. Turner, Medical Officer of Health for Cape Colony, requesting recognition of their laboratories and of the practical courses held there, for the Public Health Diploma of the Royal Colleges was referred to the Committee of Management.

A letter was read from Mr. James Robert Wallace (Editor of the *Indian Medical Record*) respecting a scheme of medical registration for India which he had brought under the notice of the General Medical Council. Sir JOSEPH FAYRER considered the proposal a reasonable one, and thought well of the scheme. Sir DYCE DUCKWORTH said that the scheme had already been before the General Medical Council, and it was understood that if it was again discussed there he would state that it had the support of the College.

A memorial on the subject of medical aid societies from the medical men of Great Yarmouth was read, and the Registrar was requested to reply to it in the same terms as the reply recently sent to a similar memorial from the profession at Norwich.

The secretary to the Senate of the University of Edinburgh reported the award of the Murchison Scholarship to Percy Theodore Herring, M.B., B.C.

Letters were read from Dr. Robert Farquharson resigning the Fellowship of the College, and from Dr. H. Llewellyn Williams resigning the Membership. The resignations were duly accepted.

A communication from his widow notifying the death of Professor Heidenhain, of Breslau (Baly Medallist, 1889), was read, and the Registrar was instructed to express the sympathy of the College with her in her bereavement.

The report of the adjudicators of the Weber-Parkes Prize was read, and permission was granted to Dr. Ransom to publish his work.

A report was received from Dr. Pavy, Sir Dyce Duckworth, and Dr. Lauder Brunton, delegates from the College to the International Medical Congress at Moscow in August last; and the thanks of the College were voted to them.

On the motion of the Registrar, certain alterations in the by-laws relating to the examinations for the Licence were adopted for the second time.

Dr. WASHBOURN then called attention to the course of study required for the First and Second Examinations of the Conjoint Board and asked for the appointment of a committee to report to the College upon the desirability of modifying the regulations with respect to the subject of elementary biology. He pointed out that the introduction of this subject in the extension of the curriculum to five years in 1892 had seriously interfered with the work of the student in anatomy and physiology, an interference not compensated by the amount of biological knowledge gained. He suggested that biology might be withdrawn, but as such a course would derange teaching another alternative might be to modify the schedule and deal with the subject under comparative physiology or else to require that biology should

Digitized by Google

be taken before the commencement of anatomical and physiological studies. He moved for the appointment of a committee to inquire into the subject and to suggest a remedy if thought desirable.

Dr. ROSE BRADFORD seconded the motion, stating that his experience as teacher and examiner led him to endorse Dr. Washbourn's remarks: he pointed out that prior to 1892 there was an examination in elementary physiology at the end of the first year.

Dr. NORMAN MOORE admitted the importance of perfecting the scheme of examinations, although he thought it most undesirable to make frequent changes in the curriculum. This scheme had only been tried for five years, and it was certainly hoped that the subjects of chemistry, physics, and biology would come to be part of the secondary education of the country. Already a number of schools had been recognised as giving the necessary instruction, and if only biology could be generally taught in such schools the objections to it as a preliminary science subject would vanish. He supported the motion.

Dr. ORD deprecated too frequent interference with the scheme of examinations; Dr. PAYNE also urged that no change should be made without deliberation and consultation with medical school authorities.

Dr. STARLING said that the introduction of biology was largely due to the belief that the additional (fifth) year of the curriculum was to be given to the preliminary sciences, but instead of that the time devoted to them was deducted from that assigned to anatomy and physiology. He characterised the study of biology by the medical student as being a "pure luxury," and said that it could not be learned properly in the time alloted, which time was therefore wasted. There was no good in trying to mend what was radically bad.

Dr. ISAMBARD OWEN considered it injudicious to lessen the amount of science required of the medical student and did not put much value on the science taught in secondary schools.

The resolution was then put and carried and the President nominated the committee as follows: Dr. Church, Dr. Gee, Dr. Payne, Dr. Norman Moore, Dr. Washbourn, and Dr. Halliburton.

The audited accounts for the year ending Sept. 29th last were presented as well as the quarterly report of the Finance Committee.

Reports were submitted from the Committee of Management and from the Laboratories Committee. Dr. Norman Moore was re-elected a member of the Committee of Management and Dr. Payne of the Laboratories Committee.

The quarterly report of the Examiners for the Licence was received, and also a list of books presented to the library during the last quarter.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE members of this association and their guests to the number of 156 dined together on the evening of Nov. 2nd, in the International Hall of the Café Monico, the President of the association, Professor A. MACALISTER, F.R.S., Professor of Anatomy in Cambridge University, being in the chair. The guest of the evening was Field-Marshal Lord Roberts, V.C., G C.B. The other guests included Surgeon-Major Sir George Scott Robertson, K.C.S.I., Dr. Sansom, the Rev. Oliver Inskip (headmaster of Framlingham), Admiral Kinahan, Mr. Robert Anderson, C.B., LL D., Mr. Butcher, Q C., M.P., Dr. Dawson Williams, Mr. Battle, and upwards of thirty ladies.

The loyal toasts having been duly honoured, Sir WALTER FOSTER proposed "The Services," and said that Irishmen took a prominent part wherever there was any fighting to be done—it was one of the glories of their race. He coupled the names of Admiral Kinahan—a genuine "son of the soil"—and Sir George Robertson, whose heroic deeds at Chitral were matters of history. The latter, in responding, paid an eloquent tribute to the bravery and genius for organisation of Irishmen in the army and made special allusion to young Harley who led the decisive sortie from Chitral; to Aylmer who won the Victoria Cross at the gates of Nilt Fort in 1891, and to Fowler's conspicuous bravery at Reshun in 1895.

Sir WM MACCORMAC, in proposing the health of the guest of the evening, said that admiration for Lord Roberts was not confined to his own countrymen, who naturally were very proud of him as an Irishmen, but was felt by every subject of Her Majesty. It was not known to many that during several days of his memorable march to Kandahar his temperature was over 100° F. His pluck in refusing then to give up the splendid task he had set himself was one of the finest things recorded in the annals of the world. The generosity of Lord Roberts in the allusions he makes in his famous book was only surpassed by the modesty with which he referred to his own actions. "No wonder," said Sir William MacCormac, "that Lord Roberts is so much beloved in the army that he is spoken of by Tommy Atkins all over the world as 'Bobs.'"

LORD ROBERTS in reply, said that the ranks, not only of the three learned professions, but of the public services were full of distinguished Irishmen, and his own experience led him to assert that Irishmen were unrivalled as soldiers, and to say from his heart that there were no better fellows in the world than army medical officers, among whom he was proud as an Irishman to recognise that a large number of the most distinguished came from "the old country." He was glad to see so many of the fair sex present and would like to ask them whether it was not the case that Irishmen made the best husbands. He was certain of this, that Irishwomen made the best of wives. It was a source of great gratification to him to know that some of the highest positions in the medical profession in England were at present occupied by such distinguished countrymen of his as Sir Richard Quain, Sir William MacCormac, Sir James Dick, and Professor MacAlister.

Dr. SANSOM proposed "Prosperity to the Association" and hoped that it would succeed in one of its objects—viz., the removal of the disability preventing the holders of Irish diplomas from competing for honorary appointments at some of the English hospitals.—Professor MACALISTER briefly replied.

Dr. PHINEAS ABRAHAM proposed "The Health of the Ladies," a toast which was responded to by Sir CHARLES CAMERON and the Rev. O. INSKIP.

The proceedings were enlivened by some excellent songs rendered by Mr. Reginald Groome and Mr. Franklin Clive.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6516 births and 3716 deaths were registered during the week ending Oct. 30th. The annual rate of mortality in these towns, which had been 16·9 per 1000 in each of the two preceding weeks, rose again last week to 17·6. In London the rate was 17·7 per 1000, while it averaged 17·6 in the thirty-two provincial towns. The lowest rates in these towns were 9·5 in Cardiff, 10·3 in Croydon, 10·5 in Leicester, and 10·7 in Brighton; the highest rates were 21 3 in Liverpool, 22·2 in Sheffield, 24·0 in Bolton, and 25·7 in Wolverhampton. The 3716 deaths included 463 which were referred to the principal zymotic diseases, against 415 and 429 in the two preceding weeks; of these, 117 resulted from measles, 98 from diphtheria, 76 from "fever" (principally enteric), 74 from diarrhœa, 55 from scarlet fever, and 43 from whooping-cough. The lowest death-rates from these diseases were recorded in Croydon, Swansea, Huddersfield, and Bradford; and the highest rates in Burnley, Halifax, Blackburn, and Wolverhampton. The greatest mortality from measles occurred in Wolverhampton, Birmingham, Burnley, Blackburn, and Halifax; from scarlet fever in Derby and Halifax; from "fever" in Blackburn, Sheffield, and Sunderland; and from diarrhœa in Burnley, Blackburn, and Preston. The mortality from whooping-cough showed no marked excess in any of the large towns. The 98 deaths from diphtheria included 65 in London, 5 in Liverpool, 4 in West Ham, 4 in Birmingham, 3 in Cardiff, 3 in Wolverhampton, and 3 in Leicester. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was

Digitized by Google

3682, against 3692, 3725 and 3685 on the three preceding Saturdays; 416 new cases were admitted during the week, against 400, 440, and 342 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 268 and 279 in the two preceding weeks, further rose to 326 last week, but were 36 below the corrected average. The causes of 47, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Bradford, Hull, Newcastle-upon-Tyne, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·1 and 20·3 per 1000 in the two preceding weeks, declined again to 19·9 during the week ending Oct. 30th, but exceeded by 2·3 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Perth and 16·6 in Leith to 23·7 in Aberdeen and 24·2 in Dundee. The 593 deaths in these towns included 35 which were referred to diarrhœa, 15 to whooping-cough, 12 to scarlet fever, 8 to measles, 6 to "fever," and 3 to diphtheria. In all, 79 deaths resulted from these principal zymotic diseases, against 84 and 86 in the two preceding weeks. These 79 deaths were equal to an annual rate of 2·7 per 1000, which was 0·5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased from 12 and 27 in the three preceding weeks, declined again to 15 last week, of which 13 occurred in Glasgow. The deaths referred to scarlet fever, which had been 17 and 4 in the two preceding weeks, rose again to 12 last week, and included 5 in Glasgow, 3 in Aberdeen, and 2 in Edinburgh. The 8 fatal cases of measles showed a slight further increase upon the numbers recorded in recent weeks, and were all registered in Glasgow. The deaths referred to different forms of "fever," which had been 6 and 13 in the two preceding weeks, declined again to 6 last week, of which 2 occurred in Glasgow and 2 in Edinburgh. Of the 3 fatal cases of diphtheria 2 were recorded in Edinburgh. The deaths from diseases of the respiratory organs in these towns, which had been 122 and 144 in the two preceding weeks, declined to 137 last week, and were 15 above the number in the corresponding period of last year. The causes of 37, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·0 and 21·2 per 1000 in the two preceding weeks, rose again to 28·2 during the week ending Oct. 30th. During the past four weeks of the current quarter the death-rate in the city has averaged 23·8 per 1000, the rate during the same period being 16·5 in London and 18·9 in Edinburgh. The 189 deaths registered in Dublin during the week under notice showed an increase of 47 upon the number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against 14 and 13 in the two preceding weeks; of these, 5 resulted from diarrhœa, 2 from scarlet fever, and 1 from diphtheria, but not one either from small-pox, measles, whooping-cough, or "fever." These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 2·4 in London and 2·3 in Edinburgh. The fatal cases of diarrhœa, which had declined from 10 to 2 in the three preceding weeks, rose again to 5 last week. The deaths referred to scarlet fever, which had been 1 and 2 in the two preceding weeks, were again 2 last week. The mortality from diphtheria also corresponded with that recorded in the preceding week. The 189 deaths in Dublin last week included 41 of infants under one year of age and 40 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded the numbers recorded in the preceding week. Eleven inquest cases and 9 deaths from violence were registered; and 70, or nearly a third, of the deaths occurred in public institutions. The causes of 11, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN DILLON assumes Medical Charge of the Departments at Portsmouth. Surgeon-Major Reade has left Woolwich for special duty in India. Surgeon-Captain Edye has taken over Charge of the Station Hospital and Detachment of No. 8 Company, Medical Staff Corps, Newcastle-on-Tyne, vice Surgeon-Major Mitchell. Surgeon-Major Beatty, M.D., has been warned to be in readiness to embark for India.

Surgeon-Colonel Charles A. Atkins retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICE.

The services of the under-mentioned officers are placed temporarily at the disposal of the Government of Bombay for employment on plague duty: — Surgeon-Lieutenant Gwyther (Bengal), Surgeon-Lieutenant Clemesha (Bengal), Surgeon-Lieutenant Rainier (Bengal), and Surgeon-Lieutenant Walton (Bengal). The services of the under-mentioned officers are replaced temporarily at the disposal of the Military Department under the Government of the North-Western Provinces and Oudh:—Surgeon-Captain Baker (Bengal), Surgeon-Captain Cadell (Bengal), Surgeon-Captain Morwood (Bengal), Surgeon-Captain Fischer (Bengal), Surgeon-Captain Manifold (Bengal), and Surgeon-Captain Young (Bengal). The services of the under-mentioned officers are replaced at the disposal of the Military Department: — Surgeon-Captain Collins, A.M.S., Surgeon-Lieutenant Morgan, A.M.S., and Surgeon-Lieutenant Howell, A.M.S.

NAVAL MEDICAL SERVICE.

The following appointments have been notified:—Staff-Surgeons: Herbert W. G. Doyne to the *Hawke*, and Octavius S. Fisher to the *Rodney*. Surgeons: Cornelius Bradley to the *Jackal*; Charles S. Bennetts to the *Lion*; Edward Cooper to the *Jaseur*; Charles R. Sheward to the *Excellent*; Eustace Arkwright to the *Alexandra*; Walter K. Hopkins to the *Pembroke*; Philip N. Randall to Ascension Hospital; George Wilson to the *Victory*, additional; Sidney H. Youel to the *Penguin*; and Morris C. Longford to the *Orlando*.

VOLUNTEER CORPS.

Rifle: 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Captain R. Grant to be Surgeon-Major. 4th Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant C. F. Glinn to be Surgeon-Captain.

DEATHS IN THE SERVICES.

Sir Rutherford Alcock, aged eighty-eight years. He entered as surgeon in the Marine Brigade which took part in the Miguelite and Carlist Wars, and eventually retired as deputy inspector-general.

Surgeon-Major-General Sir William Alexander Mackinnon, F.R.C.S. Edin., LL.D., Honorary Surgeon to Her Majesty the Queen, Knight of Grace of the Order of St. John of Jerusalem in England, at the age of sixty-seven years. He served with the 42nd Regiment in the Crimea, and was present at Alma, Balaclava, and the siege of Sebastopol (Knight of the Legion of Honour). During the Indian Mutiny he was surgeon on the personal staff of Lord Clyde. After acting as Assistant Professor of Clinical and Military Surgery at Netley he accompanied the Ashanti Expedition in 1874 as principal medical officer, and occupied the same post at Malta and Gibraltar in 1880 and the nine following years. He was appointed Director-General of the Army Medical Department in 1889, retiring on a pension in 1896.

Brigade-Surgeon-Lieutenant-Colonel John North, M.R.C.S. Eng., L.S.A., I.M.S., at Bellary, aged fifty years. He was appointed an assistant surgeon in 1869, and surgeon in 1873. He served in the Afghan War of 1879–80, for which services he obtained the medal. In 1881 he was promoted to be surgeon-major, and in 1886–87 served with the Burmese Expedition, for which he obtained a second medal, in 1889 he became surgeon-lieutenant-colonel, and in 1893 brigade-surgeon-lieutenant-colonel.

Surgeon General R. Gilborne, A.M.S. (retired), at Folkestone. He saw much service in both the Crimean War and the Indian Mutiny (Sebastopol medal with clasp and Turkish medal).

Surgeon-Major Edward John Burton (retired), at Hove, on the 31st ult. He was present at the defence of M'Carthy's

Digitized by Google

Island from an attack by a force of natives, and assisted to work the guns in action, for which service he was mentioned in despatches. He was in medical charge of a wing of the 25th Regiment during the rebellion in Ceylon in 1848, and served in the Crimean Campaign, being present at the siege and fall of Sebastopol (medal with clasp and Turkish medal).

Army Medical Manœuvres in France.

Under the orders of Surgeon-General Van Merris, principal medical officer of the Saint-Martin Hospital, some advanced manœuvres were recently carried out near Versailles, the base hospital being established in that town and the field hospital at Velizy, close to the scene of operations. The preliminary steps—that is to say, the military phase of the proceedings—bore an elementary character and did not last long, General Treuille de Beaulieu having sounded the "Cease firing" at 11 o'clock in the forenoon. This year the interest chiefly centred in the position of the field hospital. It is feared, and not without good reason, that when the most complete treatment is not immediately available a great many unnecessary deaths must take place during and after an engagement, for naturally the resources of the surgeons who have to administer first aid are limited. The object on the present occasion accordingly was to instal a fully equipped field hospital as close as was practicable to the field of battle, and, theoretically speaking, the results were excellent. A number of dressing stations were quickly organised, and the "wounded men," each of whom was distinguished by a badge whereupon was inscribed the nature of his injury, having received suitable preliminary treatment, were carried on stretchers in the first instance to an ambulance where they were further attended to, and thence, if their cases demanded it, to the field hospital, a very light litter of new pattern on wheels being successfully employed during the latter stage of the journey. For the accommodation of the field hospital a rural restaurant was utilised, the various arbours, grottoes, &c., being transformed into special wards. These bowers, destined for Parisian pic-nic parties, each had a rustic name, which did not at all correspond with the technical labels that were fixed alongside of them. As soon as darkness set in a new lamp, the invention of Dr. Maréchal, was essayed, and by its aid writing could be deciphered at a distance of 100 metres. The manœuvres were attended by a great number of medical and other officers belonging to the territorial army and the reserve, as well as by Inspector-General Dujardin-Beaumetz, Deputy-Inspector-General Dieu and Deputy-Inspector-General Chauvel.

The Nile Campaign.

We have heard uncommonly little of late from the Nile expeditionary force. The Sirdar, Sir H. Kitchener, maintains a studied reticence in regard to his intentions and movements. It is rumoured that the Khedive and the Sirdar are desirous that whatever military operations are designed should be undertaken by the Egyptian army, whereas many influential persons, whilst fully recognising the immense improvement which has taken place in that army, are of opinion that in the event of any unforeseen occurrence or reverse the Egyptian force should be backed by British troops. General Sir Francis Grenfell is now in Egypt, but it seems unlikely that he will take any active part in the advance and future field operations of the expedition. Be this as it may, the troops comprising the Nile force are, we are glad to say, healthy. Five newspaper correspondents are about to leave that force and cross the desert to Suakim, so it does not appear that any military move from Berber is imminent at present.

An Unfortunate Regiment.

The serious outbreak of cholera amongst the 1st Battalion Shropshire Regiment stationed at Sitapur shows, we understand, some signs of abating. It would seem that this regiment is fated to be pursued by the fell hand of disease, for not only have their ranks been thinned in India, but also in Malta, Egypt, and Hong-Kong. At the last-named place they were attacked by the bubonic plague while engaged in the sanitary work of cleansing infected dwellings.

The *Army and Navy Gazette* says:—"By a curious coincidence, at a time when the deficiency of instruction in tropical medicine provided by the navy for its medical officers is being pointed out, notification is made of the approval by their lordships of extensive additions to the Naval Hospital at Haslar. These will include a new zymotic hospital. The surgeons under instruction and the nursing staff are to be provided with quarters, to be erected in the vicinity of the hospital building. A new laboratory for the instruction of surgeons on entry and for bacteriological research in connexion with cases under treatment has been approved of, as well as additions to the present crowded storehouse. There is also to be a new operating theatre and improved accommodation for patients under observation for mental disease."

Correspondence.

"Audi alteram partem."

THE HOSPITALS, THE PROFESSION, AND THE PUBLIC.

To the Editors of THE LANCET.

SIRS,—The first leading article in THE LANCET of Oct. 30th raises an important point in the ethics of modern journalism: How far is the editor of a newspaper, and especially of a scientific journal, justified in making an attack upon the speech of a public man which he does not report at length? How far, too, is it proper to publish, as you do, a strong protest against the supposed views of the speaker by another speaker at the same meeting without publishing the repudiation of the views imputed to him by the speaker attacked; and how far is it justifiable to publish a letter giving at length the impressions of an anonymous writer as to what the speaker said, and then, without further evidence, to attack the speaker and hold him up to professional condemnation for statements which, in fact, he never made? Had you given a full report of my speech, which any of your readers may see if he will turn to the *British Medical Journal*, p. 1274 *et seq*, for Oct 30th, where he will find such a report, I beg leave to say, having a high appreciation from long association of your integrity and honour, that the article in question would never have appeared in the columns of THE LANCET. Circumstances having placed me in a position of authority in regard to certain questions of the first importance to the medical profession and the public—a position thoroughly acquiesced in and endorsed by THE LANCET—I have found it necessary for some years, as a matter of precaution, to have my remarks in public taken down in shorthand, so that my actual words may be forthcoming if and when challenged. I enclose you a transcript of the shorthand writer's notes of my remarks, which, in justice to THE LANCET and myself, you may like to publish.

As you regard my views as so important it may be well that I should now place them on record in your columns. They are briefly:

1. That eleemosynary medical attendance should be abolished as far as possible.

2. That hospital letters should cease to be issued in exchange for monetary contributions by hospital supporters.

3. That no patient should be admitted to the hospitals, except in cases of medical urgency or accident, without due inquiry by a qualified registration officer or almoner into the circumstances of the applicant, so as to secure that no one should receive free medical relief who was not a fit object of charity.

4. That where possible voluntary hospitals should have two sets of buildings, one set to be devoted entirely to the reception and treatment of free in- and out-patients by the medical staff attached to the hospital, and the other constituting a paying annexe (where necessary on a provident basis) to which in- and out-patients should be admitted who can afford to pay something for their medical treatment up to a fixed limit of capacity to pay, and where the in-patients can be attended, if they desire it, by their own medical men, and where the out-patient work shall be done under the direction of the medical staff with the assistance of medical officers selected from general practitioners. This arrangement would give the general practitioner in towns the advantages of hospital practice which the cottage hospitals have conferred upon his colleagues throughout the country. The whole of the patient's payments to be pooled and a certain percentage of them set aside to defray the cost of the medical attendance upon the patients in the provident annexe.

5. I am opposed to the registration fee system, which, as

Digitized by Google

the late Mr. Sampson Gamgee showed, tends in practice to exclude the deserving poor, for whom the hospitals are primarily intended, and to admit to treatment the relatively undeserving and prosperous who can pay and ought to be made to pay for their medical treatment when ill.

6. Generally, I desire to see the administration of our hospitals placed upon such a basis that they shall afford the maximum facilities for (*a*) the treatment of the really deserving poor; (*b*) the assistance of the great body of the medical profession by putting at their disposal post-graduate classes, and the adoption of a system by which the general practitioner will be encouraged to send difficult cases for consultative purposes to the hospitals; (*c*) the adoption of measures which will afford guarantees to those who provide the money for the support of hospitals that that money shall be economically administered, and that its expenditure shall be confined to the relief of fit objects of charity; and (*d*) the utilisation of hospitals as medical schools in the best interests of all classes of the people.

These are the principles for which I have worked during thirty years of my life, as my books and public utterances prove. Some may of course think, as you state, that the fact that I am not a registered medical practitioner entitles you to say that these subjects are not my proper study; but I would remind you that not only have I been practically engaged in hospital administration for thirty years, but also that I have long since completed my medical curriculum and have passed all but the final examination; that my schedules are all signed, and that I can become a registered practitioner in a few months, should that step in my judgment tend to help the cause, to the furtherance of which I have devoted all my resources and the best years of my life.

Should you, however, still contend that the principles I hold are such as to render me an unfit associate for medical men on the platform of hospital reform, I may be strongly tempted to pass my final examination, and to challenge you to stand against me at the next election for the General Medical Council, in order to prove whether the principles I advocate, or those which you somewhat nebulously suggest, best represent the opinion of medical men on this subject. I have had too many instances of the appreciation of my humble services in all branches of the medical profession to doubt in such circumstances what that issue would be; but I believe that such a contest is not likely to arise. Our views have been too much in accord to render it possible that any such conflict of opinion should exist. Your article might lead your readers to suppose the contrary, but I now show it to be based upon an entire misapprehension of my speech and views. Finally, I may say it is not my desire or intention to try experiments "on our great hospitals and our great profession," but to render them of the greatest service to each other. I am, Sirs, your obedient servant,

HENRY C. BURDETT.

The Lodge, Porchester-square, W., Nov. 1st, 1897.

*** The *British Medical Journal* reported Sir Henry Burdett as having said:—

"Could any hospital physician or surgeon who saw the cases at the hospitals deny that a very great number of cases came to them at a later period of their disease which were in a condition they ought not to be in if they had had adequate medical treatment from the general practitioner? He thought the cause of so large a number of people flocking to the hospitals was due to a want of full utilisation of the opportunities which hospitals offered not only to the public, but to the medical profession, and that they must go really into the question of the treatment of the patients outside as well as inside the hospitals if they wanted to get the question really faced."

If these words do not distinctly charge the general practitioner with incompetence we fail to see what meaning they have. As to the repudiation we disregarded it because it was no real repudiation. We print it now from the shorthand writer's notes supplied by Sir Henry Burdett.

"All I wanted to bring out is this, that as a matter of fact in the enormous body of men in general practice, especially among the class of men these out-patients go to when they do not attend the hospitals, there are a large number who would be infinitely helped both as to their practice and reputation if they would go to the hospitals and attend post-graduate classes.'

What is this but a repetition of his charge—a charge that cannot fail to damage the general practitioner in the eyes of the public? We do not believe that journalistic ethics, ancient or modern, oblige us to report Sir Henry Burdett's public utterances in full, while we stand by the sentiments expressed in our leading article.—ED. L.

"BERI-BERI AND ERRONEOUS DIAGNOSES."

To the Editors of THE LANCET.

SIRS,—In the interests of tropical medicine I desire to give my experience during my first voyage on the Peninsular and Oriental Steam Navigation Company, though the facts do not tend to throw credit on my diagnostic acumen. During the voyage a lascar came to me complaining of shortness of breath and swelling of the legs. On examination I found the œdema was not limited to the legs but extended also to the back and chest. The patient was also very anæmic. The heart was slightly dilated and the first sound was reduplicated. The lungs showed extensive emphysema, and as I found no evidence of kidney disease either in the examination of the urine or by the symptoms I concluded the œdema was entirely symptomatic of this disease, and treated the case accordingly. The symptoms and signs fluctuated from time to time, nausea and vomiting occurring occasionally, and bronchitis eventually supervening. Suffice it to say, that the patient succumbed during an attack of extreme dyspnœa. The cause of death I certified as being due to emphysema and bronchitis, never for a moment doubting the accuracy of my diagnosis. The text-book of medicine that I took with me was the well-known work of Dr. Frederick Taylor (second edition, 1891). Now the only mention in this work of beri-beri is contained in two short lines, which run thus: "Multiple neuritis also forms a part of leprosy and of the endemic disease of Japan, kak-ké or beri-beri." Taking together the fact of this altogether insufficient description and my previous clinical inexperience of the disease I feel that my error was not altogether unpardonable. Since that time, however, I have read the subject of beri-beri carefully and have also had the opportunity of seeing several cases. I have come to the conclusion that the case I have recorded was a typical case of the disease, and had I had the slightest knowledge concerning it I should have escaped making at least one erroneous diagnosis. I may say that my case is by no means an isolated one, many of a like nature having occurred to my knowledge. I can therefore fully endorse Dr. Patrick Manson's statements as to erroneous diagnosis. I consider it would be to the interest of all concerned should large companies such as the Peninsular and Oriental Steam Navigation Company make a fixed rule not to employ any medical man who could not produce evidence of having attended a course of lectures on tropical medicine.

I am, Sirs, yours faithfully,

WILLIAM BRYCE ORME, M.R.C.S. Eng.,
Late Surgeon P. and O. Steam Navigation Company.

Nov. 2nd, 1897.

To the Editors of THE LANCET.

SIRS,—*Apropos* of Dr. Curnow's letter in THE LANCET of Oct. 30th, my own experience as regards errors in the diagnosis of beri-beri quite coincides with his. Perhaps I may be permitted to cite an amusing instance from my own personal experience. In the year 1887 I was stationed in Hong-kong, and after a residence of a few months in the colony was placed in charge of the Civil Hospital for a short time pending the arrival of a newly appointed civil surgeon. A few days after I took over charge of the hospital a Chinaman was admitted suffering from what I diagnosed as locomotor ataxia; I thought some of the symptoms were anomalous, but on the whole was satisfied with my diagnosis. A few days later I was hastily summoned to find the patient (whom I had seen fairly well the same morning) sitting up in bed, and with suffused face and starting eyes gasping for breath; I had scarcely reached his bedside when he fell back dead. The necropsy showed only dilated heart. I attributed his death primarily to locomotor ataxia and more immediately to paralysis of the right heart. Next morning the old Chinese ward-master, who had worked in the hospital for seventeen years, placed the blank death certificate on my desk for signature. As I filled in the words locomotor ataxia his impassive face lighted up, and with the engaging candour of the Celestial employé he whispered in his

Digitized by Google

pidgin English, "*My* tink that peecee man die of beri-beri." In a flash I knew he was right, though, needless to say, I rebuked him for his freedom with portentous gravity.

My medical education had been no better and no worse than that of other young medical men; but at that moment and on many other occasions I had every reason to regret it had not been better. The present movement in favour of special instruction in tropical medicine is one with which every medical officer who has served abroad will be in hearty sympathy. Instances of mistaken diagnosis such as the above are innumerable, and it appears to me to be the duty of the leaders of the profession to take steps to remedy a crying need.—I am, Sirs, yours faithfully,

M. T. YARR,
Surgeon-Captain, A.M.S.

Marlborough Mansions, S.W., Nov. 2nd, 1897.

"PROPOSED AMENDMENTS OF THE NOTIFICATION ACT."

To the Editors of THE LANCET.

SIRS,—I notice in THE LANCET of Oct. 30th a criticism of a report I made to the Crewe Town Council on the above subject, and I beg to thank you for it and to acknowledge its fairness. I shall be glad, however, if you will allow me a few words of self-justification. The first point you raise is one which was modified in the memorial to the Local Government Board which was passed under the seal of this council on the 28th ult. The recommendation now reads:—

"That as one notification brings the infected premises to the notice of the medical officer of health subsequent cases of the same disease occurring in members of the same family resident in the same house, within twenty-eight days of the date of such first notification and notified by the same practitioner should be paid for at a reduced fee of 1*s.* for each case, the fee for any disease included in the Schedule of this Act other than that previously notified or for any case notified by any other practitioner to be paid for at the usual rate of 2*s.* 6*d.* per case."

I am prepared after careful consideration to stand by that as a reasonable and fair arrangement. Naturally, medical practitioners would rebel at this, but as a medical officer of health I have (to say the least) a bias towards the care of the public purse.

With reference to the second point (payment of 1*s.* as fee for notification of the milder infectious diseases) I am afraid your critic takes a wrong view of the matter. The local authority do not pay the medical practitioner for his *diagnosis*—he diagnoses the case for his *own* ends and for the satisfaction of his patient. The local authority ask him when he has made his diagnosis for these ends to acquaint them, in certain specified cases, on a form which they provide for the purpose. Medical officers of health everywhere, I venture to think, know what their reply would be if they endeavoured to persuade their local authorities to include as notifiable diseases, for which a fee of 2*s.* 6*d.* per case would have to be paid, chicken-pox, measles, whooping-cough, &c. There would in 99 per cent. of the cases be absolutely no hope of support, for the local authorities would say, "Is the information as to the existence of these milder diseases of such great value to us at present as that of small-pox, scarlet fever, or typhoid fever? No; then we think we ought not to pay so much for the information." But if we ask them to include the milder diseases at a lower fee, then there is much more hope of their giving in and the medical practitioners would benefit correspondingly.

In short, Sirs, to be perfectly plain, the medical practitioner's views of the matter are necessarily selfish and they are obviously, I think, the views of your critic; the views of the medical officer of health are for the greater part unselfish and are necessarily in conflict with those of private practitioners. There are cases (and it appears to me that this is one) in which the medical officer of health is sorely divided between his duty to his local authority and that to his medical brethren. I have endeavoured to be fair to both, and I feel confident that my brethren who are public officials will see pretty much as I do. In case you care to see it I enclose a copy of the actual memorial which has been sent to the Local Government Board by my town council, and when I tell you that this town council were strongly opposed to the Notification Act for many years and only adopted it on the repeated strong representations of my predecessor, Dr. Herbert Jones, in October, 1896 (exactly one year ago), I think you will admit that Crewe are by their recent action upholding their municipal motto, "Never Behind." I thank you, Sirs, for your anticipated insertion of this letter, and I repeat my thanks for your straightforward criticism.

I am, Sirs, yours faithfully,
MEREDITH YOUNG, M.D. Edin., D.P.H. Vict.,
Medical Officer of Health.

Health Department, Municipal Offices, Earle-street, Crewe, Nov. 2nd, 1897.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to say through your journal that I am no relation of, or in any way connected with, the man convicted of fraud at the Central Criminal Court on Oct. 29th, 1897, under the name of Theophilus Turner and described as passing as a surgeon? Theophilus was not his name at all—only one of his many aliases. I beg to say that I am the only Theophilus Bryett Turner in the Medical Register, and was very much surprised that I was not put into the witness-box to state this fact and so protect myself. Apologising for troubling you, I am, Sirs, yours faithfully,

T. B. TURNER.

"Coniston," 7, Warminster-road, South Norwood-park, Nov. 3rd, 1897.

*** We sympathise with Mr. Turner, and beg to add a protest against the loose way in which every scamp who dabbles in drugs or bone-setting to the detriment of the public health is always described on reaching the dock as a "doctor, a "surgeon," or a "medical man."—ED. L.

THE PATHOLOGY OF THE PERNICIOUS MALARIAL FEVERS.

To the Editors of THE LANCET.

SIRS,—In your report of my remarks in the discussion on Dr. Thin's paper at the meeting of the Royal Medical and Chirurgical Society on Tuesday last, I am represented as having spoken of typho-malarial fever, whereas I spoke of the æstivo-autumnal, or irregular, fever of malaria. Dr. Thin's subject was the Pathology of the Pernicious Malarial Fevers, and typho-malarial fever is not one of them.

I am, Sirs, yours truly,
J. ANDERSON.

Nov. 2nd, 1897.

THE LONDON FREE HORSE AMBULANCE SERVICE.

To the Editors of THE LANCET.

SIRS,—Will you kindly aid me in making it known to the profession that in the north, south, and south-west districts of London horse ambulances are stationed and are always available without charge for the vehicle for any case of accident or of disease which is not contagious. The costs, which in the absence of any fund have to be paid by the applicant, come in all to 7*s.*, with cab rate of increase if for over two miles. These are for the horse, 5*s.*, cleaning 1*s.*, driver 1*s.* As private ambulance carriages cost a minimum of 25*s.* to 42*s.*, this provision by the London Horse Ambulance Society will be seen to be of great help to such as are in need of it.

That this need exists has been curiously but fully demonstrated in the history of the organisation. From the time of its completion, and during my absence from England, not a single public announcement, I am told, has been made of its existence yet from an official report from each station kindly supplied to me by Sir Edward Bradford, Chief Commissioner of the Metropolitan Police, it will be seen that whereas in 1884 when the society was organised under the auspices of H.R.H. the Duke of Cambridge the carriages were used by only fourteen persons, in 1895 this number had steadily increased to one hundred and nineteen for that year and in all to nearly five hundred. On a recent inspection in detail I found each carriage to be exquisitely clean, in perfect order and in readiness to start at a moment's notice. At all the stations I found the interest displayed by the police officers in the successful use of these vehicles amounted to enthusiasm, fairly reflecting the admirable spirit of the Chief Commissioner to whose kindly coöperation the good that has been accomplished is so largely due.

The way to obtain one of these carriages is very easy. Anywhere within the metropolitan area any person desiring one has simply to state his wishes at the nearest police

Digitized by Google

station. The officer in charge at once telegraphs free of cost and the nearest carriage which is disengaged is sent direct to the spot where it is required on the conditions I have named. It is with much gratitude I am able to state that after careful investigation I have been unable to discover that there has been a single complaint during the thirteen years this organisation has been in operation.

I am, Sirs, yours faithfully,

Nov. 1st, 1897. B. HOWARD, M.D., F.R.C.S. Edin.

A HINT.

To the Editors of THE LANCET.

SIRS,—May I through the columns of THE LANCET ask the medical faculty when sending patients to the Riviera to communicate when possible first with some practitioner abroad with reference to the most suitable hotel for each case? Patients usually on arriving go direct to some hotel which they have heard recommended, often the most unsuitable, however, for them, and afterwards send for a medical man. The bronchitic may thus choose a proverbially cold hotel, the neurasthenic a particularly noisy one, and so on. It is a delicate task for the medical man to remove his patient to a more suitable hotel without straining his relations with the hotel manager who suffers, and the patient is liable to think that the trouble of re packing and moving might have been avoided by a little forethought on the part of his medical adviser before he left England. I venture to call attention to this point as it is often a matter of considerable importance to all concerned.

I am, Sirs, your obedient servant.

Mentone, Oct. 30th, 1897. D. W. S.

"THE HEALTH OF THE NAVY."

To the Editors of THE LANCET.

SIRS,—In reference to the annotation on the Health of the Navy in THE LANCET of Oct. 30th I would suggest, instead of reverting to the old plan of issuing the annual report, in which a few selected cases were included amongst a mass of statistics, that a Naval Medical Annual, separate from the present Statistical Report and compiled from the journals of the naval medical officers, be issued at a reasonable price, say 6*s*. The publication would be self-supporting, for practically every medical officer would subscribe to it, and especially if the subjects of tropical diseases and the hygiene of places visited by Her Majesty's ships be made features of the book a large number of medical men in the colonies and also at home would support it. If papers on the collateral sciences were included in the volume a great stimulus would thus be given to original research. The book would be rendered more valuable if it was illustrated with photographs and drawings and included extracts and translations from the *Archives de Médecine Navale et Coloniale* and other British and foreign journals bearing on the medical service of the navy.

I am, Sirs, yours faithfully,

Nov. 2nd, 1897. R N.

HOSPITAL ABUSE: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—Will you find space for the following suggestion in the columns of THE LANCET, where it may be subjected to the criticisms of the profession? It is that any person desiring to be treated at a hospital or other institution supported by voluntary contributions, except in cases of emergency, must produce a certificate of fitness signed by a registered medical practitioner. The objects of this proposal are obvious enough; I need not do more than capitulate them. (1) To prevent simple cases from going to the out-patient and casualty departments; (2) to prevent abuse of charities by persons able to pay; (3) to enable general practitioners to obtain quickly and easily special opinion in obscure cases amongst the poor; (4) to spare patients much weary waiting in halls and corridors—delay when they are ill and waste of time when they are not; (5) to give general practitioners opportunities of examining and taking notes upon cases which, owing to their singularity, are otherwise taken at once to hospitals; (6) to foster harmonious relations between general practitioners and hospital staffs; (7) to enable fuller family histories and histories of present disease to be obtained and to facilitate the tracing of cases after operation, &c.; (8) all which would redound to the benefit of patients; and (9) to give general practitioners more paid work to do.

The objections that I foresee will be raised are that general practitioners will take advantage of the powers given them to extract fees from the poor. To which I reply that no man can be treated against his will, and that any medical man who tried to do this systematically would soon be found out by the poor of his district. Another objection is that consultants would loose by it. Well, consultants are already in the hands of the general practitioner and have not suffered much. And also the general practitioner's certificate would only entitle a patient to treatment subject to the approval of the receiving officer of the hospital. At present there is much friction between general practitioners and hospitals because we find that our interesting cases gravitate to the hospitals, where we lose sight of them, for the patients are ashamed to tell us and the hospital authorities have no time.

The certificates might run thus:—

1. "I am of opinion that ——— ——— is a fit and proper person to receive medical (or surgical) treatment at a charitable institution.

(Signed) "———.

2. "I shall be glad of the opinion of a member of the medical (or surgical) staff of ——— Hospital upon the case of ——— ———.

(Signed) "———.

"Remarks on case ....."

There can be no doubt that this would add considerably to the amount of unpaid work that we do, as of course no medical man would charge for signing these certificates, but I think it high time that a stop be put to the ridiculous paradox of laymen forming committees to teach medical men philanthropy.

I am, Sirs, yours truly,

AN EAST-END DOCTOR.

THE EPIDEMIC OF TYPHOID FEVER AT LYNN.

(FROM OUR SPECIAL COMMISSIONER.)

IF the inhabitants of Lynn are suffering at the present moment from a serious epidemic of typhoid fever it can safely be said that they have but themselves to blame for their misfortunes. They have been warned over and over again. Nor has such warning been confined to mere theoretical dissertations; they have had more than one painful object lesson. What is occurring to-day should be all the less a surprise as a similar epidemic afflicted the town in 1892, and the story of the present epidemic seems to be written on parallel lines with that of five years ago. It appears extraordinary that the town should have waited five years and have thus incurred the heavy responsibility of provoking a second and more severe epidemic. Yet there was no lack of warning. What experience had taught was confirmed by the reports of the Local Government Board, and foretold by such local experts as, for instance, Mr. W. Whitaker, F.R.S., of H.M. Geological Survey. As President of the Norwich Geological Society this gentleman delivered an address so far back as Nov. 6th, 1883, which was fully published and reported at the time. In this address there occurs the following prophetic passage in regard to water-supply: "The enterprise of Wisbech is thus in strong contrast to the apathy, and one may say the stupidity, of the larger town, in which I have the misfortune to live, its Norfolk rival, Lynn, the corporation of which treat the inhabitants to one of the worst supplies that I know of. These guardians of the public health allow a set of chalk springs, some pure, but others contaminated, to mix together and to flow along an open channel of six miles or so as the crow flies, receiving on the way the drainage of a fair tract of country, and at the last, close by the borough boundary, some part of the sewage of the village of Gaywood. Notwithstanding that the evil of this course has been pointed out for years, and constant complaints occur, yet our town councillors, in the multitude of whom there is not wisdom,

Digitized by Google

have not yet made up their minds to any decided course of action; and a question that really admits of no debate is the subject of apparently endless discussion. Words, not deeds should be the town motto—at least, as far as regards the water-supply."

To these remarks Mr. Whitaker subsequently added: "Since the above paragraph was written the town council of Lynn adopted a scheme for the supply of good water, but I fear in a half-hearted way; at all events, their scheme has been rejected at a meeting of the ratepayers, and I am therefore compelled to transfer the charges above made from the members of the town council to the body of the townsmen, who seem not to be educated up to the pure water pitch. When they have had a serious epidemic perhaps they may acquire more sensible views on this matter."

Thus it will be seen that there were complaints as to the Lynn water-supply previously to 1883. Then nine years later follows a severe epidemic, and even this serious warning had so little effect that new waterworks are only now in course of construction, and the inhabitants are still drinking from the same impure source with which they have for so long been contented. There are thus some 20,000 persons condemned to look upon every drop of water in their houses with suspicion. The census of 1891 set down the population of Lynn at 18,265, but there has been a considerable increase since that date. Lynn is a very ancient town built on the right bank of the Ouse and can be reached by large vessels coming up the Wash. It is not only a seaport town, but a fishing town possessing a hundred or more fishing smacks. Some of the streets are very narrow, many of the houses are so old as to be of interest to the antiquarian, while narrow passages give access to back courts and overcrowded, miserable dwellings that may well be qualified as slums and rookeries. Marsh silt resting on a deep mass of clay forms the ground on which the town is built, and it measures roughly about a mile in length and half a mile in width. The general sanitary conditions are bad, the drainage is defective, and, to make matters worse, the town is water-locked. The sewer outfalls have to be closed except when the tide is up. Under these circumstances a bad water-supply is more than usually dangerous. The conditions likely to create a predisposition to disease are many, and these I hope to describe fully on another occasion. For the moment, however, I will confine myself to the most urgent question, that of the water-supply. The scheme for an improved water-supply, to which Mr. Whitaker alluded in the passage quoted above, had been prepared by Mr. Hawksley, and, according to the law, had to be submitted to a meeting of ratepayers before the sanction of Parliament could be obtained. This meeting was held in 1884, and the ratepayers forthwith vetoed the project. The matter was then dropped and nothing further was done till 1892, when an outbreak of typhoid fever more forcibly attracted public attention to the question of water-supply.

The water comes to-day from the same sources as it did during the last epidemic. No material change has been effected. It is taken from a small river called the Gaywood or Grimston River. It finds its origin in a series of springs that come from the chalk in and around the village of Grimston, some seven miles away. One of these springs arises under the churchyard of Grimston, and the inhabitants of Lynn have been content to drink the water from a cemetery. Of course, there is no accounting for taste, and it often happens that water from cemeteries is, if not wholesome, at least bright and sparkling in appearance. Doubtless, also, it may have a better flavour and be less dangerous than that coming from the privies and manured field with which it is freely mixed lower down. But this Grimston spring, even in dry weather, yields 460,000 gallons daily, and quantity is not infrequently preferred to quality. The best spring, that of Sow Head, yields only 166,000 gallons daily; but that of Well Hall, which, I believe, is also very good, yields 612,000 gallons. It was calculated that these two springs would give, even in the dryest weather, at least 700,000 gallons daily. Had this water been carefully captured at its source and brought to the town in iron mains many lives would have been saved and much sickness prevented. Nor would any injury have been done to the material interests of those who live on the banks of the stream that flows beyond. With the Grimston spring and the many brooklets and other tributary sources there would be water enough in the Gaywood River to satisfy all riparian claims. Nevertheless the springs were not utilised. The water from the Sow Head and the Well Hall springs are allowed to mingle with the water of the Grimston graveyard, and these three sources go to form the Gaywood River. On the banks of this river there are numerous and highly manured market gardens, a number of habitations, and the village of Gaywood. Not only does a part of the drainage from these places find its way into the river, but indirectly it also receives the drainage from the hamlets of Roydon, Bawsey, and Pot-row. Now, it is only after all these impurities have reached the river that we come to the intake for the water-supply of Lynn. This intake is situated within the borough, not at the beginning, but very near to the end of the river; not before the pollution, but after the pollution. In fact, considerable ingenuity seems to have been exercised in securing the most dangerous water that could be found in the neighbourhood; and the sufferers from typhoid fever are even deprived of the satisfaction of attributing their misfortune to the selfish greed of a water company hungering after big dividends. The town of Lynn owns its own water-supply. Then it may be said that the victims will, at all events, be able to revenge themselves upon the Town Council. This solace is, however, also denied them. Of late years, at least, the Town Council has striven hard to get a better water-supply. It is the ratepayers who, by their votes, have rejected scheme after scheme, yet the ratepayers of Lynn should have known better than to thus vote against their own dearest and nearest personal interests. If they would not believe the theories of sanitarians they might at least have admitted the lessons taught by their own experience. They have had the history of the epidemic of 1892–93 set before them. It is sufficiently emphatic in the lessons it conveys.

The compulsory notification of infectious diseases came into force at Lynn on March 1st, 1890, and during that year there were 4 deaths from typhoid fever. In 1891 13 cases of typhoid fever were notified. There had been deaths from typhoid fever during each of the nine preceding years, the total deaths numbering 25 from 1882 to 1890 inclusive, and there had been 75 deaths during the same period from diarrhœa and dysentery. At the end of February, 1892, there were numerous cases of diarrhœa in all parts of the town and among all classes of the community. In all, from January to June, 1892, 226 cases and 16 deaths occurred in 123 houses from what was defined as diarrhœa or fever. Subsequently 135 of these 226 cases were definitely qualified as typhoid fever. Nineteen of these cases occurred at Gaywood—that is, close to, though outside the boundaries of, Lynn. And I have reason for believing that there were many unrecognised cases of typhoid fever, so that the epidemic was in all probability more widespread than is shown by the statistics.

In 1892 there were 2300 water-closets at Lynn and 1600 privies. Out of a total of 66 houses in which there occurred recognised cases of typhoid fever, 33 drained into privies and 33 into water-closets. Thus, though the privy-houses are less numerous, they gave an equal number of cases; therefore it would seem as if privies constituted a predisposing factor. Further, it was noticed that there were a considerable number of cases of fever in the houses that drained into the dock culvert, which has its outfall closed for six hours at spring tides and for four hours at neap tides. Thus the sewage is here dammed up for several hours every day and makes deposits, and the sewer air is forced up into the streets and houses, and according to views which are now very generally held would constitute another predisposing cause. But the epidemic was so generally distributed throughout the town that, though certain predisposing circumstances accentuated its incidence in various localities, still it was evident that the epidemic was due to one distributing medium—in other words, to the water-supply, and what occurred in 1892 has again repeated itself to-day. The only difference is that the effects are worse now than they were five years ago, for the number of notified cases already amounted on Tuesday morning to 297.

(To be continued.)

COUNTY NURSING INSTITUTION FOR DORSETSHIRE.—A largely-attended county meeting was held at Dorchester recently under the presidency of Lord Digby to consider the proposed formation of a County Nursing Institution, towards which the Earl of Ilchester (Lord-Lieutenant of Dorsetshire) has promised £500 and an annual donation of £25. A committee was appointed to draw up a provisional scheme.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Corporate Supply of Diphtheria Antitoxin.

A CIRCULAR has been sent to the local practitioners from the medical officer of health's department intimating that a supply of antitoxin for the treatment of diphtheria has been provided by the Hospitals Committee at each of the five city hospitals, which can be obtained on application to the resident medical officer or matron at one or other of the said hospitals. The object which the Hospitals Committee have in view is primarily to supply antitoxin for use among the poorer class of patients; and under any circumstances the committee will be obliged if a return showing the progress of the case be made upon a form which will be supplied at the respective hospitals. This is a step in the right direction and indicates the desire of the municipal authorities to afford every facility for the reduction of infectious diseases and for placing all classes of the community under the most favourable conditions towards recovery.

Entries at University College, Liverpool.

Fifty-seven students have entered for the full medical curriculum. Eleven have joined for special courses and eleven for a dental course. Twenty-four have joined classes for preliminary instruction, making a total of 103, or 79 excluding those who have entered for the preliminary scientific course.

The Birkenhead Coroner.

Mr. Henry Churton, the octogenarian coroner of Birkenhead, has written to the town clerk intimating that owing to age and ill-health he has asked his deputy to take the Birkenhead inquests for him. The matter was warmly discussed at the recent special meeting of the Birkenhead town council, when the question arose as to the expediency of a coroner when incapacitated by age or infirmity deputing his duties to another. Upon certain members of the council suggesting a reduction of the coroner's salary it was pointed out by Alderman Deakin that although the Council had the power to fix the salary on appointment they had now no power to reduce it. Mr. Churton recently resigned the coronership of West Cheshire, which he held for upwards of fifty years, Birkenhead being included in that division of the county until it was created a borough, when Mr. Churton was appointed its first coroner. A perusal of the Coroners Act, 1892, Chapter 56, makes it doubtful whether a coroner has power to depute his work permanently to another person.

Suicide of Mr. Richard H. D. Johnson.

Mr. R. H. D. Johnson, who formerly enjoyed a moderate practice in Liverpool, but latterly practised in Birkenhead, committed suicide on Oct. 28th under very distressing circumstances. The deceased attended at the Liverpool Police-court on that date in answer to a summons issued on the part of his wife for non-payment of arrears due for her maintenance. The case was fully investigated by two city magistrates, who did their utmost to smooth matters over between the husband and wife. Their praiseworthy efforts at reconciliation proved ineffectual, as Mr. Johnson said he could not or would not pay the amount claimed. Under the circumstances the magistrates had no option but to inflict a legal penalty, which was one of two months' imprisonment in default of payment, which amounted to £142 odd. The deceased had previously suffered short terms of imprisonment for similar defaults. He was being removed to the cells in a very depressed condition, and on his way down the corridor asked the police attendant to allow him to retire as he had pains in his bowels. The request was unsuspectingly assented to by the attendant. After the lapse of a few minutes the deceased came out of the lavatory with a bottle in his hand, and addressing the police constable said, "Officer, take hold of me; I am done." He was about to fall and expired in a few moments. It was afterwards discovered that the bottle contained prussic acid, an ounce of which was sold to him by a druggist on the previous Tuesday. A verdict of suicide whilst temporarily deranged was returned by a coroner's jury. The deceased was about sixty-five years of age.

Death of Mr. William Joseph Ireland.

Mr. William Joseph Ireland died at his residence in Breck-road, where he had practised for some years, on the 22nd ult.

Nov. 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Morison Lectures.

THE first of a series of lectures on the Anatomy and Physiology of the Nervous Mechanism of the Viscera in connexion with the above lectureship was delivered by Dr. Alexander Morison at the Royal College of Physicians of Edinburgh on Nov. 1st. The lecturer discussed the methods employed by histologists in investigating the peripheral nervous system, and examined and demonstrated by microscopic preparations and lantern slides the innervation of (1) the secretory cell; (2) of the cell of involuntary muscle; and (3) of blood-vessels, especially in relation to excretion. These anatomical and physiological lectures are preliminary to a consideration of the part played by the nervous system in diseases and disorders of the viscera.

Royal Medical Society, Edinburgh.

At the meeting of this society on Oct. 29th the following were elected annual presidents: Dr. T. A. Ross, Dr. Ernest E. Porritt, Dr. H. S. Ballantyne, and Dr. George L. Chiene.

The New Pavilion for the Edinburgh Royal Infirmary.

The new pavilion, the plans for which have just been passed by the Dean of Guild Court, is expected to cost in all £40,000. It is to be situated upon the ground acquired some time ago by the managers from the directors of the Sick Children's Hospital, so that it will lie immediately to the west of the existing medical pavilions. The pavilion, excluding two four-roomed houses in the basement, will accommodate 97 persons. In its construction it is to be practically fire-proof, the floors will be constructed of iron and concrete, without wood joists, while the walls will have a lining of brick, with a space between the brick and the main wall. For purposes of asepsis there will be as little as possible in the way of door-mouldings and cornices, while all corners are to be rounded off. Ventilation is to be carried out by means of electric fans placed in a specially-designed tower. The lighting is to be by electricity. In outward appearance the pavilion will so far as possible resemble the existing ones. Internally it will consist of a basement, entirely above ground, three floors of wards of twenty-two beds each, and an attic floor. The wards are to be used for the treatment of the diseases peculiar to women, and are to be constructed with that object specially in view. In the basement is to be provided the long-wished-for bathing establishment. It will comprise a Turkish bath with three hot rooms, douche baths, needle baths, sulphur and vapour baths, while cooling rooms, attendants' rooms, lavatories, and dressing-rooms will be amply provided for. On the attic floor there are to be fourteen rooms for nurses and nine rooms for servants, besides bathrooms and lavatories.

The Edinburgh Jubilee Memorial Fund.

This fund has reached £20,000, but this is only about one-half of what is required, and another appeal has been sent out to the citizens by the Lord Provost. As the fund is to go to the extension of the Royal Infirmary and to assist the Victoria Jubilee Nursing Association it is hoped that the new appeal may bear abundant fruit.

Professor Macewen and the Western Infirmary, Glasgow.

The interest in the unfortunate conflict between Professor Macewen and the directors of the Western Infirmary continues unabated, but no progress towards a friendly settlement can at present be reported. The general feeling among the public—and it is expressed in all the local newspapers—is that whatever be the strict technicalities of the question Professor Macewen has probably been treated rather arbitrarily, and that in any case it would be a serious loss, and one not to be borne, to the infirmary and, indeed, to the whole of the Glasgow school were he to resign his position on the Infirmary staff. That such a termination of the dispute is possible is generally admitted, and Professor Macewen has intimated that he has received at least one invitation to accept a surgical appointment elsewhere.

The Faculty of Physicians and Surgeons of Glasgow.

The meeting of this Corporation for the election of office-bearers was held on Monday, the 1st inst. Dr. H. C. Cameron was elected President, and Dr. A. L. Kelly, Visitor. For an Examinership in Midwifery Dr. A. Sloan was re-elected. For the Examinership in Medical Jurisprudence Mr. T. Kennedy

Digitized by Google

Dalziel was re-elected. A contest round which much interest centred was for two vacancies in the managership of the Western Infirmary. The out-going managers, Dr. J. B. Russell and Dr. Thomas Laprair, were opposed by Dr. A. Sloan and Dr. A. Wood Smith. Dr. Russell and Dr. Sloan were elected. Dr. J. D. Maclaren was re-appointed treasurer and Dr. James Finlayson librarian.

Nov. 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Academy of Medicine in Ireland.

THE annual meeting of the Royal Academy of Medicine in Ireland for the election by ballot of the officers for the current session took place at the Royal College of Physicians of Ireland on the 29th ult., when Dr. Edward H. Bennett was elected President, in succession to Dr. James Little, whose term of office had expired. There was no other change of importance. A resolution, proposed by Dr. J. W. Moore and seconded by Sir John Banks, was unanimously passed—"That the Royal Academy of Medicine in Ireland has learned with sorrow of the bereavement of the President of the Medical Section in the unexpected death of his eldest son Lieutenant George Duffey. The Academy desires to convey to Sir George and Lady Duffey an expression of deep sympathy with them in their sorrow and of regret that so promising a career has been so sadly cut short." A similar resolution of condolence was passed by the Royal College of Surgeons in Ireland at its last meeting. Much sympathy is felt with Sir George Duffey, who is most highly esteemed by the members of his profession and by his fellow-citizens.

Royal College of Surgeons in Ireland.

The annual distribution of medals and prizes in connexion with the medical school of the Royal College of Surgeons in Ireland took place in the college hall on the 1st inst. The meeting was largely attended, the visitors including many ladies. Sir William Thomson, in his address inaugurating the medical session, took occasion to review again the claims of the officers of the Army Medical Department for improvements in that service. It will be remembered that the learned president made a most interesting speech on this subject at a recent meeting at St. Vincent's Hospital, when he mentioned that he had himself reason to believe that the Secretary of State for War was favourable to many of the claims of the army medical officers.

Death of the Rev. Professor Haughton, M.D., S.F.T.C.D.

The news of the death of Professor Haughton, of Trinity College, which took place on the 31st ult., was received in Dublin with universal regret. The learned professor was in his seventy-fifth year, but until quite recently he displayed all that wonderful energy and versatility which has rendered his name so widely known and so highly honoured. He graduated as M.D. of the University of Dublin in 1862, in 1866 he was elected a Fellow of the Royal College of Physicians of Ireland, and in 1873 a Fellow of the College of Surgeons in Ireland. After filling with much brilliancy and success many important offices in his College he became a Senior Fellow in 1882. Besides numerous purely scientific distinctions he was the recipient of many honorary degrees, that of D.C.L. Oxon. (Hon. Causâ) in 1868; LL.D. Cantab. (Hon. Causâ) in 1880; LL.D. Edin. (Hon. Causâ) in 1884; M.D. Bonon. (Hon. Causâ) in 1888; Hon. Fellow of the Royal College of Surgeons in Ireland, and of the Swedish Society of Physic.

The Typhoid Fever Epidemic at Ligoniel.

A very interesting report as to the outbreak of typhoid fever at Ligoniel, a village situate at the northern environs of Belfast, has just been presented to the board of guardians by their medical officer of health, Dr. E. C. Bigger, who, with Mr. Milligan, the dispensary medical officer of the district, has made a very careful investigation as to the cause of the outbreak. They turned their attention most carefully to two points—the milk and the water-supply. The milk was found to be supplied by about ten different vendors, several of whom came from a distance, and in only one case had there been any sickness recently amongst the family, and this milk vendor had only supplied milk to one patient. Further, very little milk was taken to the dairies, it being nearly all conveyed direct from the fields where the cows were milked to the consumers, so that the chance of its being contaminated was slight except by the water in which the cans, &c., were washed, so that the milk as a source of the infection was excluded. That there must be some common cause for the epidemic seemed likely from its sudden outbreak, for while for the past few months at Ligoniel there have been cases of typhoid fever, in common with Belfast and other places, there was nothing remarkable in the outbreak until Oct. 18th, when Mr. Milligan, the dispensary medical officer of Ligoniel, who has acted with extreme care and promptness, noticed a great increase in the number of cases attending on visiting lines. He then communicated with the sanitary authorities of the board of guardians, and on the very day he did so he received ten or twelve lines to see cases, every one of which turned out to be typhoid fever, and he considered the situation so grave that he went personally to the executive sanitary officer without waiting for a reply to his letter urging that steps should be taken to check the spread of the disease. It is admitted that the district is most defective in sanitary arrangements, but this would not account for the fact of the almost simultaneous illness of so many people. Further, the cases were more numerous in the upper part of Ligoniel where there is little or no accumulation of filth and sewage, and where there is beautiful clear mountain air. Now in Ligoniel, like Maidstone, there are two main sources of water-supply, besides several wells scattered over the district. One source supplies the upper, and the other the lower part of the village. The upper water rises out of the limestone rock from which it is piped into a large well-built underground reservoir. In this reservoir there is a large manhole, level with the adjacent ground, and it is covered over with a good-fitting, but not water-tight iron lid, and from this reservoir the water is conveyed in iron pipes down to the different fountains where the inhabitants get their supply of water for drinking and domestic purposes. Dr. Bigger, in his report, stated that in the ground above the reservoir he and Mr. Milligan proved by personal inquiry that in a house on the border of the same field there were two patients suffering from typhoid fever. One, a boy, who had been ill for a month, was getting better. His mother said she did not know what was the matter with him as no medical man had seen him. The other was a little girl who was very ill and had probably received the infection from her brother, she having been only a short time ill. Then in a house about thirty yards from this one another patient was suffering from typhoid fever. He had been ill about two weeks and his mother attributed his illness to his being a good deal with the first patient mentioned. Now the latter house was situated on the upper margin of the field wherein was the water reservoir, from which it was distant about 120 yards. All the excreta were thrown out at the back and side of the house—that is, into the same field as the reservoir, towards which there was a steep fall; and passing in front of the house there was a stream into which slops were thrown and in which soiled clothes were washed. This stream then passed along the side of a potato patch into the field, over which it flowed in the direction of the head of the spring and reservoir. Where this spring entered the field it was impassable, owing to the bogginess of the ground, but it only went a short distance down the field till it disappeared, thus showing the porous nature of the soil. This was about sixty or seventy yards above the spring which was the origin of the upper water-supply of the village. Both Dr. Bigger and Mr. Milligan think this is the probable cause of the outbreak, which may have occurred in any of the following ways. By the heavy rain which occurred two or three weeks ago washing the excreta from the back of this house and the stream directly into the reservoir through the sides of the lid of the manhole; or by the excreta and moisture from the stream being carried on the feet of the cows on to this iron lid and then being washed through the sides of the lid into the reservoir; or, what is even more probable, by the water percolating through the soil till it came to the rock which is limestone and over the surface of it till it came to the head of the spring, or through a crevice in the limestone into the spring. Up to Oct. 25th sixty cases had occurred in Ligoniel. On Oct. 23rd a sample of water was taken from three of the fountains and sent for bacteriological examination to Dr. Lorrain Smith, of Queen's College, Belfast, and after a most careful and exhaustive research in the pathological laboratory of Queen's College he has found the bacillus of typhoid fever and obtained pure cultures of it with its usual reactions, the

Digitized by Google

most recent of Widal's serum test being clearly demonstrated. This epidemic at Ligoniel is of the greatest scientific importance, both from a medical and public health point of view. (1) In a village almost simultaneously a number of people are attacked by typhoid fever in a part of the district with a high altitude and not in a bad sanitary condition, the one common nexus of the cases being that they drank of the same water-supply, which arose in the limestone rock; (2) there is the discovery of cases of typhoid fever above the origin of this water-supply and the excreta from these patients finding its way by a stream into the origin of the water-supply; and finally (3) there is the discovery of the typhoid bacillus in this water-supply (below this point of contamination) in the water coming from the fountains from which the inhabitants of the upper part of the village evidently became infected. This epidemic proves clearly that typhoid fever is in this instance a water-borne disease, and that if the water-supply had not been contaminated there would have been no outbreak; because in the part of the village supplied by another water, although there have been cases, there has been no such phenomenon as a large number suddenly and simultaneously becoming ill with the disease. The latest report is that the outbreak has not materially abated. There have been over-eighty cases, twenty-four new cases having been notified recently.

Inquest at the Cork Lunatic Asylum.

An inquest was recently held at the Cork Lunatic Asylum on an inmate who was found to have several fractured ribs, although no history of injury was forthcoming. The governors very rightly requested the Board of Control to hold a special investigation, and the results of this have now been made public. Dr. E M. Courtney, inspector of lunatics, has reported that the patient was suffering from advanced cerebral disease, and had a peculiar formation of the chest indicating a soft and brittle condition of the bones. This condition was proved to have been present by a microscopical examination made by Dr. Woods, the medical superintendent, who reported that a section of one of the fractured ribs showed an extreme degree of rarefaction of bone tissue, the cancellous spaces being filled with a very vascular and fatty cellular tissue.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Pathology and Treatment of Membranous Colitis.

M. BLONDEL recently read an important communication upon the above subject before the Therapeutical Society. According to him membranous colitis is always symptomatic and secondary. Constipation is not invariably sufficient to explain its appearance, for many who suffer from constipation never have colitis and, in addition, in many cases of colitis a prevailing symptom is acute and very painful diarrhœa. Nor is microbial infection a cause, for in the false membranes the only organism found is the bacillus coli communis. If a woman, the subject of pelvic inflammation, be also attacked by membranous colitis, it is not the microbes from the genital organs which infect the intestine for there are never found in it streptococci, staphylococci, or the characteristic gonococci, but on the other hand the existing lymphatic channels permit free passage of the bacillus coli from the intestine to the genital organs, for these bacilli are often found there. M. Blondel drew a parallel between membranous colitis and certain affections of the stomach, the rectum and sigmoid flexure which are the seats of colitis playing the same part as the stomach in that they form a reservoir with walls possessing both secretory and motor functions. In two cases observed by him there were stasis and hypersecretion accompanied sometimes by painful spasms and sometimes not, according to the type of the complaint. In colitis the hyper-secretion presents itself under a special form—namely, as a membrane—for the poured-out mucus coagulates after a little time owing to the acidity of the intestinal contents and the dehydration which occurs from the mucus remaining for some time in absorbent surroundings. M. Blondel made most of his observations on membranous colitis in women, in whom this disease is very frequent. He considers that there are two classes of causation—direct and indirect. In both classes there is a trophoneurosis both secretory and motor, due to the action of the sympathetic abdominal plexus which is excited by a reflex irritation. The indirect causes comprise all sorts of visceral ptoses which drag on the sympathetic nerves and so irritate the plexus, and the most commonly observed of these is nephroptosis, although both enteroptosis and gastroptosis act in the same way. To these must be added prolapsus of the genital organs in women; particularly retroversion of the uterus, for when this condition is present the uterus drags on the broad ligaments and their nerves and so irritates the distant plexus. It is owing to the stretching of these ligaments that pregnancy is observed as a cause of colitis about the third month, when the uterus ascends out of the true pelvis. The direct causes are the various tumours which compress the bowel and so hinder its free peristalsis, and, lastly, bands and adhesions due to old pelvic peritonitis, which knot up the coils of bowel. This is the most frequent cause of colitis in women and explains its rarity in men, for in them pelvic peritonitis is very uncommon. M. Blondel recounted many instances where the destruction of these bands, either by laparotomy or massage, had brought about the cure of a most persistent colitis. Treatment, he said, must be symptomatic, and it comprises the removal of the causes by rectifying visceral and genital ptoses and the liberation of the intestine from whatever interferes with its functions or compresses it. As to local treatment he recommended the use of large injections of a warm solution of bicarbonate of soda, strength 20 per 1000, or, still more, an injection of a 5 per cent. solution of ichthyol, which had yielded excellent results.

Responsibility for Surgical Operations.

Another remarkable case involving questions of practical surgery has just come before the law courts, but this time there is no death to be deplored. A bicyclist had been run over in the street by a vehicle. When carried to the hospital he was found to have sustained a fracture of the arm which was put up by the surgeon in charge, M. Théophile Anger. In the course of the evening the patient complained of great abdominal pain, suffered from vomiting and syncope, and presented alarming peritoneal symptoms. A surgeon having been sent for M. Hartmann saw the case, diagnosed internal hæmorrhage, and performed laparotomy. He removed from the abdomen a considerable quantity of clot and tied two mesenteric vessels which were bleeding freely. The patient made a good recovery, but as he had remained a long time in the hospital the person who had caused the accident, in order to obtain a reduction in the amount of compensation payable, argued that the laparotomy was unnecessary and that this was the sole cause of the patient's remaining so long in the hospital. M. Anger has just given evidence in favour of this strange claim before the tribunal, and said that the young surgeons of to-day are only too ready to open the abdomen. The medical world is not in favour of this evidence.

Difficulties in the Manufacture of the Alkaloids.

M. Huchard has drawn the attention of the Therapeutical Society to certain inconsistencies in the effects produced by theobromine, an alkaloid which according to him is of the most inconstant composition. It varies according to the source from which it is derived and in various cases disastrous results arise from impurities present in it. M. Bardet called attention to the difficulty which exists in France in the manufacture of really pure alkaloids at a price which permits them to compete with the foreign-made articles, more especially those manufactured in Germany. The chief cause is the extremely high price of pure alcohol in France, so that the French manufacturer has to pay 3 francs a litre while the German only pays 30 centimes, and as the evaporation of the alcohol employed as a solvent cannot be carried on at a temperature which allows it to be recovered the manufacturer necessarily suffers considerable loss. The society decided to ask the Government that all alcohols employed in pharmacy should be duty free, without much hope, however, of success, for the trade in the so-called hygienic wines containing coca, kola, &c., which are really alcoholic drinks sold in great quantities at the present day, brings in such a large revenue that it certainly would not be given up except under pressure. As there is scarcely a druggist in France who does not make these nostrums which favour intemperance under the mask of hygiene and health, it is hardly likely that the trade will renounce this lucrative industry even to gain the benefit of being able to sell pure alkaloids, which they could only sell in infinitesimal quantities and at an extremely small profit.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Serum Treatment of Leprosy.

DR. BUZZI, of Berlin, has had the opportunity of attending one of the rare cases of leprosy which happen to come from foreign countries to this city, and he has described it in the *Deutsche Medicinishe Wochenschrift*. The patient was a boy, fifteen years of age, who came from South America in 1891. He showed marked symptoms of maculo-tubercular leprosy, such as hypertrophy of the skin of the forehead, the nose, the cheeks, the chin, and the ear; on his face there were disseminated tubercles of about the size of a pea. Tubercles were also present on the extremities, and the skin, especially of the trunk, was covered with brown pigmented spots. The usual internal and external remedies proved useless. New tubercles were formed and the patient's general state became worse. Injections of Koch's tuberculin performed in 1892 were very injurious, for new eruptions followed and there was suppuration at the places where the injections were made. In 1897, when Dr. Carrasquilla, of Bogota, advocated the serum treatment of leprosy, Dr. Buzzi obtained a supply of the anti-leprosy serum, and from February to June twenty-six injections of from 0·3 c.c. to 3·25 c.c were given, the whole quantity employed being 42 c.c. The injections were given at first twice a week, then once a week, and afterwards once a fortnight only. The tissues round the place of the injections used to become œdematous; the injections themselves were rather painful, but no suppuration followed. Well-marked collapse ensued twice. Two or three hours after the injection the temperature generally rose and within eight hours reached 39° or 40° C. (102·2° or 104° F.), the commencement of the rise being marked by a rigor. During the night the temperature became normal after free perspiration, but the following day it rose again. The injections were nevertheless continued. Dr. Buzzi observed in the leprous tubercles the same alterations which were described by Dr. Carrasquilla as a sequel of his injections. The tubercles at first became swollen and were then partially absorbed, the hypertrophied tissues of the extremities decreased in size and the skin became smoother, the ulcerations of the palate and uvula healed up and those of the nose improved; the patient's weight also increased from 39½ kilos. to 45½ kilos. (from 87 lb. to 100 lb.). The treatment has now been discontinued for about four months. Some new tubercles which appeared during and after the treatment were spontaneously absorbed. Although it is still uncertain whether the improvement will continue the injections of serum have so far yielded results which are much better than those obtained by any other method of treatment.

Anesin, a Substitute for Cocaine.

In a good many cases the administration of cocaine becomes impossible owing to an idiosyncrasy of the patient. This fact, together with the danger of acute poisoning, has induced Dr. von Vamossy, assistant in the Pharmacological Institute of Budapest, to search for a substitute, and in the *Deutsche Medicinische Wochenschrift* he recommends a compound which in chemical terminology is called trichlorpseudobutyl-alcohol, or aceton-chloroform, whilst its pharmacological name is anesin. The drug itself has been known for a long time, but the difficulty of preparing an aqueous solution has hitherto hindered its practical use. Dr. von Vamossy has, however, succeeded in making a solution which he tried in the first instance on rabbits. He found that a solution of a strength varying from 1 to 2 per cent. when applied for one minute to the cornea of a rabbit produced an anæsthesia lasting from eight to ten minutes, while an application for three minutes caused an anæsthesia of several hours' duration. Subcutaneous injections made the tissues so insensible to pain that the animals endured incisions two or three centimetres (from ¾ in. to 1¼ in.) in depth without uttering cries, and from fifteen to twenty subcutaneous injections produced general anæsthesia. The substance was then tried by several physicians and surgeons who communicated their observations to the author. Professor Froni, who used it in laryngological practice, said that the sensibility of the pharynx and larynx becomes reduced by brushing the mucous membrane, and that the nasal mucosa may easily be made insensitive in this way when operations with the galvano-cautery are to be performed. Dr. Grosz, ophthalmic surgeon, stated that mere dropping of anesin on the conjunctiva was less efficacious than cocaine, but an application continued for one minute produced total superficial anæsthesia. Subcutaneous injection enabled extirpation of the lacrymal gland to be performed without pain. The remedy produces neither mydriasis nor myosis. Dr. Hültl has used it in general surgery, the operations being herniotomy, resection of the mandible, extirpation of carcinoma of the lip, removal of lipoma, extraction of teeth, &c. His opinion is that the application of the drug is very easy; that it acts as an anæsthetic, but only as far as the tissue is permeated by the solution; that the duration of the anæsthesia is equal to that of cocaine; and that no symptoms of poisoning have been observed. In dental practice it was tried by Dr. Bilasko, who found that in 160 extractions of teeth there was no pain at all in 45 cases and only slight pain in 44 cases; whilst in the remaining 71 the pain was somewhat greater. Dr von Vamossy invites medical men to try the new remedy, which, although in some respects less efficacious than cocaine, has undoubtedly some advantages, especially that of absolute freedom from danger.

Immunity against Anthrax.

Dr. Sobernheim, assistant in the hygienic institute of the University of Halle, has published a paper in the *Berliner Klinische Wochenschrift* in which he states that the blood serum of animals immunised after Pasteur's method against virulent cultures of anthrax bacilli as well as that of those which have recovered from a spontaneous infection does not contain any immunising substance. The blood of animals, however, which have been immunised by increasing doses of anthrax cultures for several weeks undergoes certain alterations which make them resistant against anthrax bacilli of strongest virulence. When from 4 c.c. to 10 c.c. of the blood serum were injected into rabbits they survived injections of anthrax culture, which killed other rabbits in from thirty-two to forty hours. This immunity, however, was only a relative one, as the animals died several days afterwards, a fact at variance with the observations of Selass and Marcheux, of the Pasteur Institute, who secured absolute immunity by injections of only 1 c.c. or 2 c.c. The use of serum obtained from sheep which had been immunised against cultures of strongest virulence was also a failure, as no complete immunity could be imparted to rabbits. But the experiments were much more successful in the case of sheep, for all the sheep which were injected with blood serum of immunised animals became immune against infection by the most virulent culture of anthrax bacilli. The only pathological symptom was a transient rise in the temperature and an infiltration round the place of the injections. All the sheep to which the same quantity of anthrax bacilli had been administered without a previous injection of serum died after a few hours. The serum of artificially immunised sheep is therefore a propbylactic against anthrax infection.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Congresses: Medical, Surgical, and Special.

THERE is no keeping pace with Italy's congresses, central and provincial, particularly in the late autumn. I can overtake them only in swallow-fashion, skimming and dipping. The "Congresso della Società Italiana di Medicina Interna" (the eighth of the series) was held at Naples from Oct. 20th to 24th and was chiefly memorable for the theses on "Leukæmia and Pseudo-leukæmia," introduced by Dr. De Renzi and Dr. Marchiafava; on "Chronic Arthritis," introduced by Dr. Fenoglio and Dr. Massalongo; and on the "Cardiac Neuroses," introduced by Dr. Cardarelli and Dr. Silva, the last-named a very important paper, as will appear on its publication in the official "Atti" (proceedings). A feature of these congresses of internal medicine is the "Esposizione" of medicaments and therapeutic appliances annexed to them; and this year's exposition was an improvement on the best of its forerunners. Another and still more comprehensive congress was that held in our University from Oct. 25th to 27th, at which the opening address was delivered by the Senator F. Durante, professor of surgery in the Roman school. "Congresso dell' Ordine dei Medici" (Congress of the Guild of Practitioners) was its title, and an infinite number

Digitized by Google

of questions relating to the interests of the profession in Italy was raised and discussed by its members. Prominent among these was Dr. Santini's Bill, "Sull' Esercizio Professionale dei Medici Stranieri in Italia." But as its provisions are known to the readers of THE LANCET and as its discussion at the Congress added no new argument in its support to those already adduced (and, let me say, refuted), I content myself with indicating its place on the agenda-paper. Of the special congresses, that of the "Obstetric and Gynæcological Practitioners" closed on Oct. 21st, and that of "Otology and Laryngology," also held here, under the able presidency of Professor Grazzi, and closed on Oct. 30th, need alone be mentioned. The official reports of all these congresses, containing the more memorable papers (with relative discussions) *in extenso*, are now in the press and will see the light at the close of the present or in the course of the ensuing year.

The English-speaking Practitioner in Italy.

A circular has been addressed by the Minister of the Interior (the Marchese di Rudini, Prime Minister) to the prefects throughout the kingdom. It is neither more nor less than a mandate charging these functionaries to invite all non-Italian dentists to furnish proof that in addition to their home qualifications they possess one from a recognised qualifying body in Italy, failing which these gentlemen are to be held as practising illegally, are therefore to be called upon to desist from practice, and in the event of their being contumacious to be denounced to the judiciary authority.

Oct. 31st.

Obituary.

SURGEON-MAJOR-GENERAL SIR W. A. MACKINNON, K.C.B., F.R.C.S. EDIN., &c.

HONORARY SURGEON TO THE QUEEN, LATE DIRECTOR-GENERAL OF THE ARMY MEDICAL DEPARTMENT.

THE death of Sir William Mackinnon, the late Director-General of the Army Medical Service, on Oct. 28th, at his residence in Evelyn-gardens, S.W., at the age of sixty-seven years, removes a notable personality as well as a distinguished medical officer. The health of Sir William Mackinnon had not for some time past been altogether satisfactory, and especially during the latter part of his service as the head of his department; but he was a man of fine physique and vigorous aspect, and his death must have come as a shock and surprise to his numerous friends. He had occasionally complained of symptoms attributable to kidney trouble and recently of others referable to cardiac affection, with occasional attacks allied to angina; but he was fairly well during the earlier portion of the day of his death, which was at the last sudden and unexpected, pulmonary symptoms having supervened which were partly excited or aggravated by the fog. The late Sir William Mackinnon's record of war service was a long, varied, and distinguished one; he was a strong and very energetic man—a man of action—and always took a leading part in any duty in which he might be engaged. His varied field service in different parts of the world brought him in close and intimate contact with a number of military officers of rank and distinction from the days of Lord Clyde to the present time, with whom he was a general favourite. This was also attributable to his frank and outspoken, but genial manner. He enjoyed a very wide circle of acquaintance and possessed considerable personal interest with the late Commander-in-Chief and other influential people. By temperament he was somewhat impulsive, but that his instincts and impulses were honest and kindly by nature there can be no doubt, otherwise he would not have made so many friends, to whom his loss will be a grief. He was strongly attached to his profession and in his younger days took an active and even ardent part in surgery and in keeping himself *au courant* with all advances in that direction. Sir William Mackinnon was the son of the late Rev. John Mackinnon, of Strath, in the Isle of Skye. He was born on June 27th, 1830, and was educated at Glasgow and Edinburgh Universities, being admitted a Licentiate of the Royal College of Surgeons of Edinburgh in 1851, and elected a Fellow in 1872. Enter ng the Medical Department of the Army in February, 1853, he served throughout the Eastern Campaign of 1854–55 with the 42nd Highlanders (the Black Watch), including the battles of Alma and Balaclava, in medical charge of the regiment, took part in the expedition to Kertch and Yenikale, in the siege of Sebastopol and the assault of the Redan (Sept. 8th) and in the final fall of the fortress, for which he had the medal with three clasps, the Knighthood of the Legion of Honour, and the Turkish medal. He next saw active service in the Indian Mutiny and in the New Zealand War. He took part as principal medical officer in the second phase of the Ashanti War of 1873–4, when he accompanied the force to Coomassie. In 1879–80 he was principal medical officer in China, obtaining the rank of Surgeon-General in May, 1880; serving in Malta from 1880 to 1882; at the War Office from 1882 to 1888, and at Gibraltar in 1888–9. In 1889 he was appointed to succeed Sir Thomas Crawford as Director-General of the Army Medical Department, resigning that position last year. He had been in receipt of a good service reward from 1885, was made a K.C.B. in 1891, and was appointed Honorary Surgeon to the Queen in February, 1893.

We have been favoured with the following note upon Sir William Mackinnon by one who knew him well: "In Sir William Mackinnon passes away a striking personality. His Highland origin and Celtic temperament furnished him with that enthusiasm for all he was interested in and the impetuosity of character, always anxious for the truth and all that was good, which endeared him to so many and which secured for him throughout his career troops of admiring friends. His mind was simple and sympathetic and his actions transparent in their honesty and good intentions. Usually quiet in demeanour, he would flash with excitement at anything which hinted wrong or injustice of any kind to anybody. For everything belonging to his profession he had the keenest interest and enthusiasm, and most especially for the surgical branch of it. The catalogue of his military career does not mention that in the early part of it he abandoned medicine for a short space to enter as a fighting officer in a Highland regiment, but he soon returned to his old allegiance. Whenever opportunity arose, as it oftentimes did in the course of his extraordinarily long period of active military service in the Crimea, the Indian mutiny, and New Zealand, he never failed to do some good operative surgery. He performed several excisions of the elbow in the last-named country when that operation was just being introduced afresh to surgical notice—so well abreast was he of the time. At the storming of the Gate Pah a characteristic incident occurred. The officers were one by one wounded or killed, and none remained unhurt but Mackinnon. He took command of the men, rushed the Pah, captured it, and in so doing necessarily killed and wounded the New Zealanders. Several of these he afterwards dealt with as a surgeon, being obliged to amputate in some cases limbs where he himself was solely accountable for the damage he was engaged in rectifying. He might have had a V.C. at this time, but chose the C.B. instead—a circumstance he often regretted. At the time of the Ashanti War, under Lord Wolseley, he failed to be nominated for a place in the expedition. Yet without orders, or perhaps against orders, he went to Madeira so as to be as near as practicable to the scene of action, and Sir Anthony Home, the principal medical officer, falling sick, Mackinnon at once started for the Coast, reported himself to Lord Wolseley, who was very glad to welcome him, and accompanied the expedition to Coomassie as its chief medical officer. This gives some notion of his resourceful energy. He was essentially a man of action. He loved his strictly professional duties, but administration and office work were distasteful to him."

A memorial service was held at St. Columba's Church, Pont-street, on Tuesday, at which both the Duke of Cambridge and the Duke of Connaught were represented, while Field Marshall Sir Donald Stewart and Sir Frederick Haines were in the church. On the same day the remains were cremated at Woking, the service being conducted by the Rev. G. Kirkwood, Chaplain to the Forces, and the ashes will be deposited in the family burying-ground at Kilchrist. Her Majesty the Queen sent the following gracious message to Sir William Mackinnon's family: "Please convey to the relatives of the late Sir William Mackinnon the expression of the Queen's sympathy in their loss sustained by the death of that distinguished officer and member of Her Majesty's Household.'

PROFESSOR MARC OLIVET.

NOT since Moritz Schiff died rather more than a year ago[1] has Swiss medicine sustained a severer loss than that of Dr. Marc André Olivet, Professor of Psychiatry in the University of Geneva. Son of the able Genevese surgeon, M. François Olivet, young Marc André gave early proof of aptitude for the medical career, and after the thorough preliminary education so rigorously exacted in Switzerland he pursued his professional studies in the University of Würzburg, where in 1842, when just in his twenty-first year, he graduated with the "summi in medicinâ honores." Thereafter he proceeded to Lyons and to Paris, and at both seats of learning distinguished himself by his assiduous attendance at the cliniques of their most eminent teachers. It was only after some years thus profitably spent that he embarked on general practice, first at Satigny and afterwards at Geneva. In the latter city his predilection for pure medicine soon asserted itself; he was appointed *médecin en-chef* of the Cantonal Hospital, a post he held for four years, and later accepted the eminently responsible duties of *médecin-en-chef* of the Hospice des Vernets, where he had need of all the tact and the administrative as well as clinical powers with which nature had richly endowed him. He held this position for the thirty-two years between 1856 and 1892 during which the transformation of the Genevese Asile d'Aliénés was passing through its successive phases, and his discharge of the complex and often peculiarly trying *rôle* vouchsafed him was in all respects nothing short of exemplary. From this service his appointment to the supplementary chair of Psychiatry in the University of Geneva was almost a "natural transition," and in due course he succeeded to the post of ordinary professor in the same subject. This was in 1882, and when the Federal law imposing increased stringency on the admission of students of medicine to graduation and practice came into force he was chosen a member of the Directing Committee of Examinations throughout the Confederation. In this capacity he insisted on the candidate's possession of practical knowledge, and it is greatly due to his influence that medicine has made itself so beneficially felt in the aggregate life of the Swiss population, commencing at school and extending to every industrial or mercantile employment, demanding the coöperation of many hands. For the eight years during which he sat on the Administrative Council of Geneva he was the advocate, equally persistent and enlightened, of school hygiene, a subject which interested him deeply even in advancing age and declining health, in so much that he did not disdain the onerous if comparatively humble duties of sanitary inspector of the infant schools of the city.

Dr. Olivet has left a high reputation in medical and particularly in hygienic literature, his monographs and more fugitive publications on hygiene as applied to school-life, to pedagogy, to agriculture and such like, amounting to not a few volumes. "Thorough" is the attribute written large over all these compositions, characteristic as they are of his penetrating insight, sound judgment, and mastery of detail. It is, however, as a clinical observer and teacher that his memory will be most warmly cherished in the Geneva school, where he has left behind a record of acute diagnosis and judicious therapeutics rarely surpassed in the difficult and delicate field of medicine he had made his own. Ill-health withdrew him from professional work about a year ago; but, as is often the case, the unwelcome inactivity thus imposed seemed to assist the malady which it was meant to avert. He died on the 24th ult. in his seventy-sixth year.

JOHN HUGHES, F.R.C.S. ENG., L.S.A., J.P.

MR. JOHN HUGHES died at Penrheol, Barry, on Oct. 27th. Mr. Hughes was born in North Wales in March, 1818, and received his medical education at St. Bartholomew's Hospital, London, taking the M.R.C.S. Eng. and L.S.A. Lond. in 1840, and the F.R.C.S. Eng. in 1858. Mr. Hughes spent the greater portion of his life at Carmarthen, where he was for twenty-five years one of the leading practitioners. He was surgeon to the Carmarthen Infirmary, medical officer of health for the Carmarthen district, surgeon to the prison, and was also a magistrate for the borough. Five years ago on his retirement from practice he removed from Carmarthen to Barry and resided with his son, Mr. J. A. Hughes, the town clerk of Barry. The deceased leaves three daughters and another son, the Rev. Hugh Price Hughes, M.A. Mr. Hughes was beloved by all who knew him, and was held in the highest esteem. Much sympathy is felt for the widow and children, the former of whom is in ill health. The funeral took place at Merthyr Dovan Cemetery on Oct. 30th.

[1] Vide THE LANCET, Oct. 24th, 1896, p. 1198.

ANDREW HINGSTON, M.R.C.S. ENG., L.S.A., J.P.

MR. ANDREW HINGSTON died at Liskeard, Cornwall, on Oct. 21st in his seventy-seventh year. The deceased received his medical education at the London Hospital, and took the qualifications of M.R.C.S. Eng. and L.S.A. in 1842. Mr. Hingston was consulting surgeon to the Liskeard Hospital, and had been medical officer of health of the Liskeard urban district. He was also a Justice of the Peace for Liskeard and about thirty-five years ago was mayor of the borough.

Medical News.

H.R.H. THE PRINCE OF WALES, K.G., has been graciously pleased to accept a copy of the print of the Council of the Royal College of Surgeons of England (1884) as a memento of the Jubilee year.

HIGH SHERIFF OF BRISTOL.—Mr. R. F. Richardson Cross, M.B. Lond., F.R.C.S. Eng., surgeon to the Bristol Eye Hospital, has been nominated for the office of High Sheriff of Bristol for 1897-98.

BRISTOL ROYAL INFIRMARY.—The Bristol Royal Infirmary has recently been benefited to the extent of £20,000. This sum was bequeathed by the late Miss Martha Daubeny to Mr. E. Sampson, of Henbury, for life, but upon his death had to revert to the institution.

TYPHOID FEVER IN CLIFTON.—At the meeting of the Bristol Sanitary Authority, held on Oct. 28th, Dr. D. S. Davies, the medical officer of health, reported that in the week ending Oct. 23rd two cases of typhoid fever were notified in Bristol and sixteen in Clifton, and that two deaths had occurred; the notifications in Clifton from Oct. 23rd to Oct. 28th numbered twenty-five. The inhabitants are recommended to boil all milk before use, as observation of the cases indicated a connexion between the disease and milk-supply. Dr. Davies says there is no reason to suspect the public water-supply.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—A meeting of the town-hall committee of the Cardiff town council was held on Oct. 28th, under the presidency of Alderman Carey, to consider the application made by the University College of South Wales and Monmouthshire for a site for the college and museum in Cathays Park. The chairman stated that the corporation had subscribed £10,000 towards the building fund of the college, and the committee would be prepared to recommend that a site should be provided on condition that the college authorities paid for the land at the same proportion as it would cost the corporation. On the motion of Dr. Buist, seconded by the mayor, it was resolved that a site be granted on the terms mentioned by the chairman.

BOURNEMOUTH MEDICAL SOCIETY.—The annual meeting of this society was held at the Imperial Hotel, Bournemouth, on Oct. 27th, Dr. Roberts Thomson, the retiring President, being in the chair. The report and balance-sheet were taken as read and passed. Dr. Thomson then thanked the members for the honour accorded to him in electing him President during the past year and vacated the chair in favour of the President-elect, Mr. A. G. S. Mahomed. The new President proposed a vote of thanks to Dr. Thomson, which was carried with acclamation. Mr. Heygate Vernon was elected as treasurer, Dr. W. H. L. Marriner as librarian, and Dr. Clift as honorary secretary. The following were elected members of the committee: Dr. Masters, Dr. Marriner, Dr. Muspratt, Dr. Ramsay, and Dr. Duncan. Twenty-five members and three guests sat down to the dinner which followed.

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—The first meeting of the session was held on Oct. 30th at the St. George's-in-the-East Infirmary. Several matters connected with infirmary administration were discussed. Mr. Burney gave notice that at the next meeting he would move that the society should subscribe to the Royal Medical Benevolent College.

AT a meeting of the British Balneological and Climatological Society (Dr. Snow, of Bournemouth, President), held on the 27th ult. at 20, Hanover-square, Mr. A. H. Haviland proposed, "That the establishment of a chair of Medical Climatology and Geography is desirable." This was seconded by Dr. C. Theodore Williams and carried unanimously. It was then proposed that the subject should be referred to the council, and a committee be formed to consider how best the above resolution should be carried into effect.

DISEASED ANIMALS IN MANCHESTER.—During the year ending Aug. 28th, 1896, there have been four outbreaks of glanders in Manchester. Seven glandered horses have been killed and the carcasses destroyed. At a cowshed at Rusholme, where 35 cows are kept, one became affected with anthrax and died. Four outbreaks of swine-fever have occurred, and the 234 pigs on the different premises were all slaughtered by order of the Board of Agriculture. A special inspection of the cowsheds in the city—112 in number—and also periodical examinations of the milch cows—1182 in number—have been made by the veterinary staff. Of the latter 29 had tuberculosis, and 23 of them were slaughtered by the owners, while the others were dealt with by the medical officer of health.

DIPHTHERIA IN LONDON.—The amount of diphtheria recorded in London during the four-weekly period ended on August 14th—namely, 1111 notified cases, which fell during the succeeding four weeks ended on Sept. 11th to 866 notified cases, has been exceeded by the returns for the like period ended on Oct. 9th when 1169 cases were notified. Whilst the weekly average of the September period was 216 cases, the average in the October period was 292; and all the sanitary districts save one were invaded, three having been free in the September period. Also, whilst four districts in the September period had upwards of 50 cases each, and an aggregate of 246, there were seven such districts in the later period, with a total of 469 attacks. As a set-off against this there were other five districts with only 17 notified cases amongst them. The 117 deaths (29 weekly) in September rose to 182 (45 weekly), in the later period, the respective case-mortality rates being 13·5 and 15·6 per cent. Thus the latter half of September and the first part of the current month furnished not only an excessive amount of diphtheria in London, but also saw the disease in a more fatal form. Matters have not tended to mend in the three weeks ending on Oct. 30th, during which 165 deaths were registered in the county of London, in addition to 57 deaths in the outer ring. In the week ended Oct. 16th, the 45 registered deaths were one below the corrected decennial average, and also a decline on the former weeks with their respective total of 49 and 53; but the cases notified numbered 351. Only 1 death occurred in infancy, and only 1 of a person aged over twenty years, 23 being of children aged from one to five years. Kensington, St. Pancras, and Lambeth sanitary areas had each 4 deaths, and Westminster, Islington, Bethnal Green, Newington, and Plumstead sanitary areas had 3 deaths each. In the suburbs 3 deaths occurred in West Ham, 5 in Hendon, and 4 in Edmonton registration districts. In the week ended on Oct. 23rd, the 55 deaths registered in London were three in excess of the corrected decennial average, 6 being of infants and 2 of persons aged over twenty years. Islington was credited with 6 deaths, Hackney and Battersea each with 5, and Camberwell with 4 deaths. The close of the week found 1057 patients suffering from the disease in London hospitals. In the outer ring, of the 16 deaths, 6 occurred in West Ham, and 4 in Hendon registration districts. Last week the number of deaths registered from diphtheria in London increased to 65, this total being 17 in excess of the corrected decennial average for the particular week. Only one death occurred in an infant, other 43 in children in the next four years of life, and not one in a person aged over twenty years. Seven deaths were credited to Poplar, 6 to St. Pancras, 5 to Bethnal-green, 4 each to Battersea, Camberwell, and Greenwich, and 3 each to Fulham, Hackney, and Plumstead sanitary areas. In the outer ring 21 deaths were registered, of which 7 belonged to West Ham, 5 to Edmonton, and 4 to Hendon Registration Districts.

THE sum received this year in aid of the amalgamated charities by the Birmingham Hospital Sunday Collection amounts to £4010 0*s.* 7½*d.*

MEDICAL DEPUTY-LIEUTENANT.—Mr. William Hamerton Jalland, F.R.C.S. Eng., of York, has been appointed a Deputy-Lieutenant by the Lord-Lieutenant of the West Riding of the county of York.

SIR SQUIRE BANCROFT has promised to give a reading in Cardiff on Dec. 3rd, in aid of the Seamen's Hospital and the Infirmary. He will also give another at Torquay on Jan. 25th, on behalf of the Torbay Hospital.

WE have received from Mr. R. B. Anderson, acting as honorary secretary of the Corporate and Medical Reform Committee, a copy of a letter sent by the committee to Dr. Glover. In this it is stated that Dr. Glover's letter was based on "entire misrepresentation" and "entire misconception" of the circular issued by the committee. We have received from Dr. Glover a letter in which he maintains the justice and accuracy of the reflection contained in his letter published in THE LANCET of Oct. 23rd, and declines further correspondence.

THERAPEUTICAL SOCIETY OF MANCHESTER.—The first meeting for the session 1897-98 was held at the Owens College on Oct. 27th, Professor D. J. Leech, president, being in the chair. Dr. J. S. Bury described a case of Toxic Symptoms following the administration of a large dose of Phenacetine, and a short discussion took place upon the toxic effects of the synthetic antipyretics. Dr. Fothergill gave a short account of the Uses of Senecio Jacobæa, and showed specimens of the plant and preparations made from it. Mr. Kirkby also forwarded an account of the mode of preparing a Liquid Extract of Senecio, which was an effective and convenient form for its administration. Dr. A. T. Wilkinson read an interesting paper upon certain desirable Additions to the Pharmacopœia which would greatly enhance its value to medical practitioners. Dr. Yonge showed a sample of Orthoform, a newly introduced local anæsthetic.

THE ANGLO-INDIAN ASSOCIATIONS.—Dr. James R. Wallace, editor of the *Indian Medical Record*, visited England not long ago for the purpose of bringing the cause of the Anglo-Indian Associations under the notice of the public in the mother country. He returned to India in September, having met with gratifying success in the carrying out of his objects, and on the 27th of that month a large number of ladies and gentlemen of the European and Anglo-Indian community assembled in the Bombay town-hall for the purpose of welcoming him back. After some introductory remarks by the Rev. Isaac F. Row, president of the association, who occupied the chair, Dr. Wallace said that in Great Britain hardly anything was known of the domiciled British community in India, meaning by that term the section of the population consisting of Europeans of every nationality and their descendants, who had made India their home. The various methods by which the condition of this community might be improved were fully explained by him to several members of Parliament in the House of Commons and to members of the Government at the India Office and the War Office. Among the points to which he especially directed attention were the exclusion of the domiciled community from imperial appointments, the raising of local regiments, and the desirability of classifying Europeans and Anglo-Indians as British in the cases where British nationality was a requisite for holding an appointment. In conclusion, four resolutions were adopted, the first of which was as follows: "Resolved that this meeting of the domiciled European and Anglo-Indian community of Bombay, held in the town-hall on Monday, Sept. 27th, 1897, cordially appreciates and approves of the various measures that have been adopted by Dr. James Robert Wallace, as the delegate of the Anglo-Indian Associations, for the advancement of the interests of the resident British community of India, by suitable representations of their cause to Parliament and to the India Office in London, and this meeting records its hearty thanks to Dr. Wallace for his disinterested and praiseworthy labours on behalf of his countrymen during the past six months in London."

HEFFERNAN.—On Oct. 25th, at Grove House, De la Warr-road, Bexhill, the wife of Harold Hilton Heffernan, M.R.C.S. Eng., L.R.C.P. Lond., of a son.

HILLS.—On Oct. 26th, the wife of A. Phillips Hills, M.R.C.S. Eng., F.S.Sc., at Carlton House, Prince of Wales-road, Battersea-park, S.W., of a son (John Fletcher Twycross).

RICKETTS.—On Oct. 27th, at The Warren, Greenhithe, Kent, the wife of Thomas Frank Ricketts, M.D., of a daughter.

STEWART.—On Oct. 25th, at York House, Fulham-road, S.W., the wife of Eland Stewart, L.R.C.P. Lond., M.R.C.S., of a son.

MARRIAGES.

MARTIN—CAMPBELL.—On Oct. 26th, at St. Giles's Cathedral, Edinburgh, John L. Martin, M.B., C.M., Chelmsford, Essex, to Matilda, second daughter of Alex. D. Campbell, Bellevue-crescent.

DEATHS.

BOOTH.—On Oct. 31st, at Westfield-terrace, Aberdeen, Jas. Booth, M.D., M.R.C.S., in his 79th year.

BURTON.—On Oct. 31st, at Salisbury-road, Hove, Brighton, Edward John Burton, M.D., Surgeon-Major, late Army Medical Department.

DUFFEY.—On Oct. 13th, 1897, at Jamaica, of yellow fever, aged 25 years, George Allan, Lieutenant 1st Battalion the West India Regiment, elder son of Sir George Duffey, M.D., President of the Royal College of Physicians of Ireland.

GILBORNE.—On Oct. 28th, at Fairlawn, Folkestone, Surgeon-General R. Gilborne, J.P., late of the 89th Princess Victoria's Regiment and of the 6th Dragoon Guards (the Carabiniers), aged 73.

GILLESPIE.—On Oct. 31st, at Sir George Bowles's Hospital, Butleigh, suddenly, William Henry Gillespie, L.R.C.P., L.R.C.S. Irel., aged 50 years.

MACKINNON.—On Oct. 28th, 1897, at Evelyn-gardens, S.W., aged 67, Surgeon-Major-General W. A. Mackinnon, K.C.B., Hon. Surgeon to the Queen, late Director-General Army Medical Department.

PHILLIPS.—On Oct. 27th, at 2, Spital-square, George Bagster Phillips, M.R.C.S., L.M., L.S.A., aged 63.

SHEPPARD.—On Oct. 29th, at Randolph Lodge, West Worthing, Edgar Sheppard, M.D., D.C.L., late Professor of Psychological Medicine, King's College, London, aged 78 years.

STOCKWELL.—On Nov. 2nd, at 7, Queen's-parade, Bath, Thos. Goldesbrough Stockwell, F.R.C.S., L.R.C.P., L.S.A., aged 74.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (10th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), ing's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (11th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (13th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (8th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Dr. A. E. Sansom (President): Two Cases of Mitral Stenosis.—Dr. W. S. Colman: A Child with Cretinoid Physique without Mental Defect.—Dr. W. Carr: Sporadic Cretinism Cured by Thyroid Extract.—Mr. C. Mansell Moullin: Two Cases in which Inoperable Tumours have almost disappeared under the Administration of Coley's Fluid.—Dr. F. de H. Hall: Case of Obesity.—Mr. G. Templeton: Case of Multiple Subcutaneous Tumours.—Mr. W. H. Battle: Congenital Syphilitic Affection of the Knee in the Adult.

TUESDAY (9th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—Papers:—Mr. P. J. Freyer: Obscure Cystic Tumour of the Bladder containing Two Calculi, Successful Removal by Suprapubic Cystotomy.—Mr. F. Eve: On Mesenteric Cysts, with Two Cases in Young Children; Operation.

WEDNESDAY (10th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—Papers:—Dr. Herman: Pruritus Vulvæ.—Dr. F. J. Smith: Medical Hæmorrhage.

SOUTH-WEST LONDON MEDICAL SOCIETY (Wandsworth Town Hall).—8.30 P.M. Paper:—Mr. P. J. Freyer: Stone in the Bladder, Symptoms and Modern Methods of Diagnosis, the Modern Instruments employed in Litholapaxy, being a Review of 900 Operations for Stone by all Methods.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Cases and Specimens will be shown by Dr. J. Donelan, Dr. J. B. Ball, Mr. W. R. H. Stewart, Mr. M Agar, Dr. J. W. Bond, Mr. W. G. Spencer, Dr. W. Hill, Mr. M. Yearsley, Dr. J. Horne, Dr. S. Spicer, Mr. E. W. Roughton, Dr. H. Tilley, Mr. W. Wingrave, and Dr. Pegler.

THURSDAY (11th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-sq., W.).—8 P.M. Card Specimens. 8.30 P.M. Papers:—Mr. C. Wray: The probable Rôle of Heredity in the Development of Myopia and the way in which it is Modified by Disease.—Surgeon-Capt. H. Herbert: Some Matters of Interest in Cataract Extraction.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Specimens will be shown by Mr. Bowerman Jessett and Mr. O'Callaghan. Adjourned discussion on Mr. Keith's paper on Dysmenorrhœa. Paper:—Dr. J. A. Shaw Mackenzie: Hæmorrhagic Endometritis.

FRIDAY (12th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. A. H. Tubby and Mr. R. Jones: Some Cases of Pott's Curvature of the Spine treated by Immediate Reduction of the Deformity (followed by lantern demonstration of the method).—Mr. A. Pearce Gould: A Case of Acute Intestinal Obstruction relieved by Operation, Death from Intestinal Toxæmia on the Ninth Day after Operation.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

MONDAY (8th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. C. Wilkin: Nasal Polypi.

TUESDAY (9th).—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Alcoholic Insanity; Insanity with Syphilis; Insanity with Organic Brain Disease.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Scabies.

HOSPITAL FOR NERVOUS DISEASES (73, Welbeck-street).—4.30 P.M. Dr. T. D. Savill: Cases of Paraplegia.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Tooth: On Spinal Cord Lesions (with lantern demonstration)

WEDNESDAY (10th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Sanitary Appliances.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. P. Kidd: Pleurisy.

EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Dr. F. Willcocks: Clinical Cases from the Wards. (Post-Graduate Course)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. A. Whitfield: Medical Cases.

THURSDAY (11th).—ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Savoy, W.C.).—5 P.M. Dr. Pavy: Points connected with the Pathology and Treatment of Diabetes. (Supplementary to the Croonian Course delivered in 1894)

LONDON POST-GRADUATE COURSE.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. R. Barwell: Clinical Lecture.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Colman: Demonstration of Selected Cases.

FRIDAY (12th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Actinomycosis and Glanders.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE INFANTS' ASYLUM ON RANDALL'S ISLAND, NEW YORK CITY.

IN *Pediatrics* of Sept. 1st there are some strong remarks on the management of the Infants' Asylum on Randall's Island. The fact that it is unhealthy in a high degree to herd young children together in large numbers has been conclusively proved and emphasised time after time. The foundling hospitals in Italy and some of the children's hospitals in France (notably l'Hôpital Trousseau in Paris) are conspicuous examples of the dangers attending this course, and doubtless there are in England some instances of a similar kind. *Pediatrics* says: "From an investigation of the affairs of the 'Infants' Asylum at Randall's Island,' which until a few months ago was under the control of the city, the truth has been made public that the mortality among the infants reaches the fearful rate of nearly 90 per cent. Before the institution was handed over to the management of the Commissioners of Charities matters were even in a worse state than now, and it was stated on the authority of the medical board that to enter it under the age of six months was certain death." From the foregoing account it will be gathered that the asylum at Randall's Island is in almost as bad a sanitary state as are Italian foundling hospitals. However, it is satisfactory to learn that vigorous efforts towards reform are to be made by the Charity Commissioners, assisted by the mayor, and without doubt now that public opinion has been aroused the institution will be placed on a better sanitary footing.

C. S. J.—Colonial appointments are in the gift of the Colonial Office. Application should be made to the private secretary of that office before the end of the first quarter in any year. The applications for these appointments greatly exceed the vacancies. The posts of medical visitors in lunacy are in the gift of the Lord Chancellor. Certain appointments are also made by the Local Government Board and the Board of Trade, to each of which bodies our correspondent should apply.

DIGRAPHIC COPY-BOOKS.

WE have received from Dr. Robert B. McVittie, of Dublin, a specimen of a series of copy-books designed with a view of teaching longhand and phonography simultaneously. Shorthand now occupies a prominent place in the learned professions, but as a rule the subject is not taken up by the student until that period of his life when, owing to the multiplicity of the subjects of his professional curriculum, he can ill spare the time. Practically the mental effort required to trace the preliminary characters of the phonographic alphabet is little more than that required for the drawing of pothooks and hangers, and long before a child has gone through the complete series of books he should, with intelligent teaching, be able to use phonography with some degree of utility. The books are published by M'Caw, Stevenson, and Orr, Loopbridge, Belfast, and by Sir Isaac Pitman and Sons, London.

INSTRUCTION IN ETHICS.

To the Editors of THE LANCET.

SIRS,—I have sometimes thought it would be a good thing if a chair of medical ethics could be established in our leading schools of medicine. It seems that at present no teaching of medical morals is provided for the rising generation of practitioners, and yet to most thoughtful minds such an institution would surely commend itself. It may not be out of place at this particular season to consider how much the plain teaching of professional morality would have effect in giving a healthy tone to the eager but undisciplined energies of those entering on the threshold of professional life. Most of us whose lives have been given to the practice of the healing art can look back on the past with very chequered feelings as regards the nobility of our calling; suffice it to say that in spite, or as a natural sequence, of much that has been mooted touching the proprieties of professional conduct the general outlook is decidedly unpromising. I venture to affirm that the professional tone fifty or sixty years ago was higher than it is at present. It may be true that competition was less keen, that life was generally more pleasant and easy, and that the general strain was less severely felt; but still the code of professional honour and integrity was more generally recognised and respected. The rush and struggle of modern times, in which the strong and unprincipled tread down the weak and self-respecting, the gladiatorial combats which make and mar our rising, pushing race, give to the holy calling of medicine a sanguinary hue. As a medical man remarked to me the other day, it is a throat-cutting business. Let me instance a few examples. In the town where I live a medical man had engaged a residence in a favourable locality and some distance from any other practitioner. He had scarcely taken the house before two other professional "brethren" applied to the landlord for it, offering a much higher rent with other pecuniary advantages to secure possession. One of these lives a mile off, and the other half a mile from the spot. Another medical man makes a custom of buying practices for the sole purpose of selling them after a year or two. In a country practice I once held a man in a neighbouring town placed an unqualified assistant, whom he dubbed "doctor," in the village eight miles from his own residence to steal my practice from me. He used to call on my patients, stating I was about to leave and asking for their support. He also canvassed my clubs, offering lower terms. I brought the matter before the General Medical Council and they replied they could take no action as he was not registered. Such instances of unprofessional conduct are perhaps known to most of your readers; I need hardly enlarge upon them. In attacking the abuse of medical charities and club organisations we are making clean the outside of the platter while within it is full of uncleanness and abomination. But I have trespassed too much on your space. Excuse, Sirs, the opinions of. Yours faithfully,

A PRACTITIONER OF OVER FORTY YEARS' STANDING.

Oct. 11th, 1897.

INSTRUCTIONS TO THE PUBLIC ON INFECTIOUS DISEASE.

A DISCUSSION lately took place before the Hexham sanitary authority on the propriety of issuing certain rules for the guidance of those responsible for the management of cases of infectious disease. The medical officer of health disapproved the indiscriminate issue of such instructions in a town where everybody is supposed to have a medical man to guide them in such circumstances, supported—as he should be—by the medical officer of health. The actual rules sent us are defective and would lead in our view to mischief. The chief duty of a parent or guardian with a case possibly infectious is to send immediately for a medical man, on whom should rest the responsibility of instructions as to isolation and disinfection. There is not a word to this effect in the rules, whereas much that would be misunderstood and give the readers a notion that they were doing right is contained in them. We agree that some plain rules, to be drawn up by the medical practitioners and medical officers of health, might with advantage be prepared and distributed by the practitioner in attendance at his discretion; but they should be simple and few, and of such a nature as to assume the presence and supervision of the practitioner. We think the sanitary authority did well to be guided in this matter by their medical officer of health.

THE OVERCROWDING OF THE PROFESSION: A TIME-HONOURED COMPLAINT.

A CORRESPONDENT writes: "Looking through an old volume of the *Spectator* some time ago I came across an article by Addison on the overcrowding of the professions. It is dated March 24th, 1710. I was surprised to find that this supposed modern question is at least nearly 200 years old, and as the paper may not be widely known I give one or two quotations from it:—

"I am sometimes very much troubled, when I reflect upon the three great professions of divinity, law, and physic; how they are each of them overburdened with practitioners, and filled with multitudes of ingenious gentlemen that starve one another. * *

"If we look into the profession of physic, we shall find a most formidable body of men. The sight of them is enough to make a man serious, for we may lay it down as a maxim, that when a nation abounds in physicians it grows thin of people. ..... This body of men may be described like the British army in Cæsar's time. Some of them slay in chariots, and some on foot. If the infantry do less execution than the charioteers, it is because they cannot be carried so soon into all quarters of the town, and dispatch so much business in so short a time. Besides this body of regular troops, there are stragglers, who, without being duly listed and enrolled, do infinite mischief to those who are so unlucky as to fall into their hands.....When I consider how each of these professions are crowded with multitudes that seek their livelihood in them.....I very much wonder at the humour of parents, who will not rather choose to place their sons in a way of life where an honest industry cannot but thrive, than in stations where the greatest probity, learning, and good sense, may miscarry. How many men are country curates, that might have made themselves Aldermen of London, by a right improvement of a smaller sum of money than what is usually laid out upon a learned education? A sober frugal person, of slender parts and a slow apprehension might have thrived in trade, though he starves upon physic; as a man would be well enough pleased to buy silks of one whom he would not venture to feel his pulse..... The misfortune is, that parents take a liking to a particular profession, and therefore desire their sons may be of it: whereas in so great an affair of life, they should consider the genius and abilities of their children more than their own inclinations. It is the great advantage of a trading nation, that there are few in it so dull and heavy, who may not be placed in stations of life, which may give them an opportunity of making their fortunes. A well regulated commerce is not, like law, physic, or divinity, to be overstocked with hands; but on the contrary flourishes by multitudes, and gives employment to all its professors.

"Fleets of merchantmen are so many squadrons of floating sheets, that send our wares and manufactures in all the markets of the world, and find out chapmen under both the tropics."

Mr. L. Moscrop.—We do not recommend individual practitioners or treatment.

THE BURN OF SEALING-WAX: WANTED A REMEDY.

To the Editors of THE LANCET.

SIRS,—Some time ago I read of a French chemist who burned his hand with sealing-wax and found accidentally that some chemical compound, the nature of which I have forgotten, gave him instant relief when applied to the affected part. Having recently had a most aggravated case I would be grateful to any of your correspondents to refresh my memory as to what the remedy was.

I am, Sirs, yours faithfully,

JOHN R. WILLIAMS, M.R. Edin.

Bryn Hyfryd, Penmaenmawr, Oct. 30th, 1897.

THE jury of the Great International Exhibition at Brussels have awarded "Le Grand Prix" to Messrs. J. S. Fry and Sons, Limited, for their pure concentrated cocoa and other specialities.

LUMINOUS LIFE-SAVING APPLIANCES.

A JOURNEYMAN tile-maker of Compiègne named Bouraine, who is an active member of the Oise Humane Society, has invented a system for illuminating life-buoys, rafts, and other appliances for saving life from drowning, which has recently undergone successful trial at Compiègne, Rouen, and also in Paris. The invention consists in the attachment of small incandescent electric lamps to the appliance, one or more according to size, the illumination being maintained by means of an accumulator which is said to be capable of acting for seven or eight hours. As soon as the buoy or raft touches the water an indiarubber bladder moves a lever, and the circuit being thus established the lamps at once become luminous. In concluding his notice the writer in a Parisian medical journal makes the following observation: Steam vessels at the present time are all fitted with the electric light, and it would be easy to keep the small accumulators constantly charged. If only M. Bouraine's ingenious invention had been available in the tragical shipwreck of the *Drummond Castle*, what a number of valuable lives would have been saved.

REV. J. E. LONDON AND THE MEDICAL PROFESSION IN BRITISH GUIANA.

IT was our duty some six months ago to point out that a Georgetown paper, in referring to the impending presence of the Rev. "Dr." J. E. London at a banquet given to Lord Lister by his junior colleagues, had miscalculated Mr. London's importance. The Georgetown paper seemed to think that to be invited to the dinner was an especial social and scientific honour, whereas all Lord Lister's house surgeons and clinical clerks were bidden to the feast. And inasmuch as such a view would tend to exalt Mr. London, a King's College man, at the expense of other medical men in British Guiana not qualified to be invited, we pointed out that it behoved Mr. London publicly to correct the false impression. Did Mr. London ever do this? We have recently had sent to us a copy of the *British Guiana Congregational Magazine*, which contains under the title of "Echoes from Afar" Mr. London's speech at the "Royal Café, Regent-street, London, W.C.," on the occasion of the dinner in question. Appended to this speech is an address of congratulation to Lord Lister, signed by certain medical men in British Guiana. Of these gentlemen we now desire to ask as follows. Did they know that Mr. London was going to incorporate into his speech, made presumably on their behalf, a eulogy of himself and his "colleagues, Dr. Deane and Dr. Wills, in our Public Dispensary and private practice"? Is this particular Public Dispensary notably the home of Listerian principles and antiseptic surgery?

If *A Subscriber* will consult the Students' Number of THE LANCET, p. 513, published on Aug. 21st, 1897, he will find a list of the benevolent agencies of the profession, together with all necessary particulars.

THE CLIMATE OF SOUTH AFRICA AND PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Will any of your readers inform me if they consider it advisable to send a man suffering from phthisis in the early stage to South Africa, and if so, what place they would recommend in preference? The patient is a middle-aged man and would like to undertake some light employment if his health permitted. Any information on the matter from your readers acquainted with South Africa would be very acceptable. Thanking you in anticipation for publishing this letter, I remain, Sirs, yours faithfully,

C. G. BATTISCOMBE.

Rowlands, St. Mary Cray, Kent, Oct. 21st, 1897.

Dr. Wyckoff.—No such article has appeared in our columns. Rome has undergone no "improvement" from an "improved water-supply," for the water-supply has at all times been superlatively good—a bequest from the ancient Romans, whose fourteen magnificent aqueducts have for centuries been represented by at least five, more than sufficient for the city's wants, and the envy of other cities for the purity of the water they bring. Certain old rookeries, like the Ghetto, have been replaced by better constructed, better ventilated dwelling houses, and hygienic regulations (chiefly re-vaccination) have also contributed to heighten the standard of health. During the sittings of the Eleventh International Congress in 1894 our Special Correspondent contributed a series of articles on how to see Rome, but sanitary indications in them were merely incidental. Our correspondent will perhaps find all the information he wants on a reference to the best authorities bearing on it in Dr. Mendini's "Hygienic Guide to Rome," recently translated by Mr. Eyre, and reviewed in THE LANCET.

E. A. S.—It would be advisable that the family should not reside in the house during the alteration. The risks may be remote, but they are real. These remarks especially apply if any member of the family is of delicate health.

SURGICAL OPERATIONS ON DOGS AND CATS.

IN an interesting paper read at Manchester on Sept. 30th Professor Hobday, F.R.C.V.S., of the Royal Veterinary College, gave an account of the following operations as performed on dogs and cats: excision of the membrana nictitans, the operations for entropion, the operative treatment of hæmatoma of the ear-flap, amputation of everted rectum, amputation of limbs, laparotomy, laparo-enterotomy, ovariotomy and oöphorectomy, hysterectomy and ovaro-hysterectomy. During the last three years amputation of limbs has been performed in the College Clinique fifteen or sixteen times, one of the patients being a valuable whippet dog, both of whose forelegs were removed just below the elbow. He is now kept solely for stud purposes, and when walking has an appearance very like a kangaroo. Creolin in some form is the surgical antiseptic most commonly used in the College Clinique.

ENGLISH AS SHE IS WROTE.

THE following letters were recently addressed to a practitioner in India and have been sent by him to the *Indian Medical Record*:—

I.

To ——— —— Esq. Medl. Practr. Respected Sir,—I am sorry that I am badly suffering by cold fever and therefore cannot come to work for 2, 3, days for which I pray your honor will not cut my pay and will excuse. I am poor man, but if you do, then I must be damn and come to work at once. Reply by bearer my maternal uncle will oblige.—Your obedient servant N. K.

II.

To Mr. Dr.————Esq. My dear doctor saheb,—I am sorry to inform you that I am suffering from fever and coldness coming upon me like hot sun's rays falling upon a man's eyes balls. By this I am cannot attend my duty, feeling very giddy and my headache is too much paining, feeling my body all paining. Vomitions by mouth and private part are too many, and by this I am feeling too much hungry and weakness and cannot take food because every food I take becomes just like a rheumatism. Something is also rising upon my whole body like bowels. Please send effective medicine, etc.—Your, respected sir obedient servant V. V———.

These specimens of Baboo English are not unworthy of addition to the many others that have from time to time appeared in print. Nor do we reproduce them in ridicule, for there is an adventurousness about their use of the English language which commands the respect due to gallant effort.

ICHTHYOL AND GLYCERINE SUPPOSITORIES.

To the Editors of THE LANCET.

SIRS,—It is now an established fact that ichthyol is a most valuable remedy in a large number of uterine diseases, not only taken internally, but applied mixed with glycerine, which is also a valuable therapeutic agent, in the form of a vaginal tampon. There are a great many obvious disadvantages in the use of the tampon, so I have had ichthyol and glycerine suppositories for vaginal application made by Messrs. Wyley, of Coventry. They are more effective and much easier of application than the tampon, they can be used by the patient, and the speculum not being necessary they are particularly adapted for use in disorders occurring in the virgin. There is 10 per cent. of ichthyol in each suppository and they can be had in different sizes. I see no reason why they should not also be valuable for rectal medication.

I am, Sirs, yours faithfully,

J. LESLIE CALLAGHAN, L.R.C.S.Irel., L.R.C.P. Ed., L.M.

Coventry, Oct. 27th, 1897.

*** Mr. Callaghan enclosed samples of well-made suppositories of different sizes.—ED. L.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Newport Advertiser, Sussex Daily News, Walsall Advertiser, Bedford Times, Salisbury Journal, Lincolnshire Echo, Sheffield Telegraph, Times of India, Pioneer Mail, Glasgow Herald, Manchester Guardian, Dundee Advertiser, Devon Gazette, Midland Mail, Builder, Bromley Telegraph, Elgin Courant, North British Daily Mail, Yorkshire Post, Times of Africa, Kentish Observer, Bridgwater Independent, Leeds Mercury, West London Observer, Herald of Wales, Hereford Times, Liverpool Daily Post, East Anglian Times, Vegetarian, Bristol Times and Mirror, Worcestershire Chronicle, Hastings Observer, Bristol Mercury, Architect, Luton Reporter, North Wilts Herald, Blackburn Standard, Leicester Post, Birmingham Gazette, Lowestoft Standard, Southport Visitor, Wolverhampton Chronicle, Portsmouth Times, New York Times, Mail and Express (New York), Sanitary Record, Local Government Chronicle, Mining Journal, Reading Mercury, Weekly Free Press and Aberdeen Herald, City Press, Hertfordshire Mercury, Surrey Advertiser, Local Government Journal, St. Bartholomew's Hospital Journal, Yorkshire Herald, Lincoln Gazette, Blackburn Times, West Middlesex Herald, Scotsman, Public Health, Witney Gazette, Strathearn Herald, &c., &c.*

Digitized by Google

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Mr. F. C. Abbott, Lond.; Argentum, Lond.; Mr. B. D. E. T. Archer, Worthing; Messrs. J. and R. Archibald, Tillicoultry; Mr. T. Annandale, Edinburgh.

B.—Dr. A. O. Bobardt, H.M.S. *Dart*, Cooktown; T. B. Browne, Ltd., Lond.; Surgeon-Capt. W. J. Buchanan, Bhagalpur; Messrs. Burgoyne, Burbidges, and Co., Lond.; Messrs. W. H. Bailey and Son, Lond.; Mr. S. H. Benson, Lond.; Bristol General Hospital, Secretary of; Dr. F. L. Benham, Lond.

C.—Mr. A. E. W. Clarke, Sestri Levante, Italy; Surgeon-Capt. Cockerill, Lydd; *The Canada Lancet*, Toronto, Manager of; Miss M. Canning, Lond.; Messrs. J. and A. Churchill, Lond.; Mr. A. H. Cheatle, Lond.; Messrs. Carnrick and Co., Lond.; Cortland Wagon Co., Lond.; Cymro, Lond.; Dr. R. H. P. Crawfurd, Lond.; Mr. F. S. Carter, Leeds; Mr. W. F. Clay, Edinburgh; Dr. S. T. Champion, Burgess Hill; Mr. T. Cooke, Lond.; Dr. H. Campbell, Lond.

D.—Mr. S. L. Dobie, Dunain Park; Dr. A. V. Davies, Bridgend.

E.—Dr. W. M. Elliott, Strabane; Messrs. Eason and Son, Dublin; Mr. W. G. Earle, Tunbridge Wells.

F.—Dr. W. S. Fenwick, Lond.; Mr. C. L. Fraser, Berwick-on-Tweed; Messrs. Fairbairn and Sons, Edinburgh; Dr. Fleming, Stockton-on-Tees; Mr. P. V. Fry, Farnworth; Messrs. Ferris and Co., Bristol; Formalin Hygienic Co., Lond.

G.—Dr. W. J. Gow, Lond.; Dr. H. B. Girdlestone, Lond.

H.—Mr. S. Harding, Whittlesea; Mr. S. Hertz, Lond.; Hôtel du Nord, Bad Nauheim, Proprietors of; Dr. A. Harper, Eastbourne; Dr. J. Holmes, Manchester; Mr. J. Heywood, Manchester.

J.—Mr. P. N. Jones, Lond.; Mr. H. H. Jennings, Lond.

K.—Dr. H. R. Kenwood, Lond.; Kurhaus, Lond.; Mr. E. Knight, Lond.; Dr. G. E. Keith, Lond.

L.—Mr. T. J. Lipton, Lond.; London Central Exchange; Mr. T. Leadbeater, Birmingham.

M.—Mr. S. Moscrop, Brighton; Surg.-Lt.-Col. Mackenzie, Abbottabad; Mr. H. M. Murray, Lond; Mr. F. P. Munday, Lond.; Dr. Moynihan, Leeds.

N.—National Telephone Co., Lond., District Manager of; Nurses' Hostel Co., Lond.;

P.—Dr. E. B. Porritt, Edinburgh; Dr. F. W. Pavy, Lond.; Messrs. Parke, Davis, and Co., Lond.; Mr. J. Pond, Norwich; Dr. F. J. Poynton, Lond.

R.—Revolution Cycle Co., Dublin; Royal South Hants Infirmary, Southampton, Secretary of; Royal College of Surgeons, Dublin, Registrar of.

S.—Mr. J. W. W. Stanton, Southsea; Salford County Borough, Town Clerk of; Messrs. Street and Co., Lond.; Messrs. Smith, Elder, and Co., Lond.; Sister Josephine, Ramsgate; Student, Lond.; Mr. T. Smith, Lond.; Dr. F. Spicer, Lond.; Dr. E. M. Skerritt, Bristol; Student, Willesden Green; Dr. A. D. Silveira, Key West, U.S.A.; Dr. D. J. Sherrard, Hailsham; Mr. W. Stockwell, Bath; Surgery, Lond.; Mr. A. Stenhouse, Glasgow; *The Scotsman*, Edinburgh, Publisher of.

T.—Mr. J. Thin, Edinburgh; Messrs. W. Thacker and Co., Lond.; Messrs. Teff and Co., Bristol; Sir W. Thomson, Dublin.

U.—*University of Pennsylvania Press*, Philadelphia.

V.—Mr. J. W. Vickers, Lond.

W.—Messrs. Wright, Layman, and Umney, Lond.; Mr. T. Woodruff, Lond.; Mr. S. Wand, Leicester; Mr. C. A. V. Winfield, Lond.; Wilson's Advertising Offices, Glasgow; West Bromwich District Hospital, Secretary of.

B.—Messrs. Brown, Gould, and Co., Lond.; Messrs. R. Bentley and Son, Lond.; Borough of Bury, Treasurer of; B. D., Lond.; Boscombe Hospital, Secretary of; Messrs. Blondeau et Cie, Lond.; Bedford General Infirmary, Secretary of; Mr. H. Birmingham, Charters Towers; Mrs. E. Bennett, Braunston; Blackburn and East Lancashire Infirmary, Secretary of; Mr. E. H. Beaman, Misterton; B. D., Lond.; Mr. C. Bridges, Lond.; Mr. R. Burnett, Leek; Beta, Lond.; Mr. R. J. Bedford, Kegworth; Brin's Oxygen Co., Lond.; Barum, Lond.

An Address

ON

EXPLORATION OF THE INGUINAL CANAL, WITH SPECIAL REFERENCE TO LIPOMA OF THE CORD, INGUINAL VARIX, CONGENITAL HYDROCELE, AND RETAINED TESTIS.

Delivered before the Nottingham Medico-Chirurgical Society on Oct. 20th, 1897,

BY C. B. LOCKWOOD, F.R.C.S. ENG.,

ASSISTANT SURGEON AND LECTURER ON ANATOMY, ST. BARTHOLOMEW'S HOSPITAL; SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL, ETC.

MR. PRESIDENT AND GENTLEMEN,—Having opened the inguinal canal 180 times it may be easily understood that certain unexpected contents have been encountered. I propose to begin by describing cases in which fatty tumours were found instead of the hernial sac which was supposed to be there. These lipomata are not infrequently mistaken for ruptures and are sometimes treated with trusses. For instance, a postman was declined for promotion until he had had double inguinal ruptures cured. On the right side I found the sac of an incomplete inguinal hernia with some varix of the spermatic veins. On the left side he had an impulse on coughing and a swelling which could be reduced into the abdomen. This was also thought to be an incomplete hernia, but when the inguinal canal was opened a lipoma of the cord with varix of the spermatic veins was found, but no hernial sac. The fat and the veins were excised. For some years this man had worn a double inguinal truss; two years after the operation his right side was perfect; on the left side, where he had had the lipoma, he had occasional pain in the testis, but nothing whatever to account for its existence. Another youth was operated upon, having been rejected for the army because he had a hernial impulse in both inguinal canals. When the inguinal canals were opened I found a small hernial sac in the left and a small lipoma in the right. Eight months afterwards he was quite well. Yet another man had radical cure of hernia performed on each side to enable him to remain in the army. Unlike the other two he had hernial sacs on both sides together with a rather large lipoma in the left. He returned to the army after he had been operated upon. In one of my earlier cases I omitted to remove a fair amount of fat from the inguinal canal of a youth who was operated upon for a left inguinal epiplocele. On reflection this omission caused me much regret. It is obvious that its removal would have involved no danger whatever, whereas its presence would interfere with the valvular closure of the inguinal canal.

Here I will for a moment digress to remark that so far as my own observation goes the mechanism of the inguinal canal is not at all well understood. I confess that I did not myself at all appreciate it until during the course of my operations I had had many opportunities of seeing it in action. If during the operation for the radical cure of hernia a young and vigorous adult coughs, vomits, or struggles when the inguinal canal is open, it is easy to see how the arching fibres of the internal oblique and transversalis muscles descend upon the spermatic cord and squeeze it against Poupart's ligament. The spermatic cord itself is clearly the bar to the complete closure of the canal, and much more so would be a mass of fat or a bunch of dilated veins, or a hernial sac of any kind. The exact relation of these fatty tumours to the causation of hernia is, I believe, unknown. They are often situated at the lowest end of the sac, and it seems reasonable to suppose that by distending the inguinal canal they facilitate the descent of a hernia. As regards their origin there can be little doubt but that they are merely pieces of sub-peritoneal fat which have descended with the testicle. This can easily be seen occurring in any male fœtus at about the ninth month. The not infrequent occurrence of these lipomata seems to me to render it highly desirable to open and explore the inguinal canal when performing the operation for the radical cure of hernia. It is probable that, as a rule, they can only be diagnosed by an operation, and until this has been done the patient is under the impression that he has a rupture, and may perhaps, as in the cases I have mentioned, be in danger of losing an appointment. All of my cases occurred in adults. I have not yet seen a lipoma of the cord in a child apart from hernia. But whilst helping a colleague to operate upon a little boy both a hernial sac and a lipoma were found in the inguinal canal. The lipoma was large enough to form at least a medium-sized bubonocele.

I have already referred to the fact that in some of the foregoing cases of lipoma of the cord the veins of the spermatic cord were also varicose. I now propose to refer to some cases in which the dilatation of the spermatic veins within the inguinal canal was so great as to simulate a hernia. It is easy to understand why this is so when it is known that the varix or varicocele gives rise to a swelling which appears when the patient stands up, disappears when he lies down, and has an impulse on coughing, and which, moreover, causes a pain which closely resembles that of a hernia. Moreover, a scrotal varicocele is nearly always absent, so that it is very hard indeed to tell the inguinal varix from an incomplete hernia. One day I began to operate upon a youth, as was thought for the cure of double inguinal hernia. The right canal contained nothing but a group of enormously dilated spermatic veins exactly like a large scrotal varicocele; the left contained a similar group together with a small empty hernial sac. These veins were excised and the sac was treated in the usual way. I regret to say that this proved to be one of the very few cases of radical cure which have caused me any anxiety. On the third day I found this youth blanched, with a rapid pulse and distended abdomen. As there was much induration about the left inguinal region together with a swelling in the iliac fossa I explored the wound. A huge blood clot was removed from the iliac fossa, and more blood was found in the peritoneal cavity. This intra-peritoneal hæmorrhage was drawn off with a glass drainage-tube above the pubes. The source of the hæmorrhage was not discovered. He made a complete recovery after an anxious illness. The right side healed by first intention, and the left was packed with antiseptic gauze. This is the only case of mine which has been complicated with hæmorrhage, but how far it was related to the varicose veins I do not know. It is quite possible, and not improbable, that I had transfixed one of the deep sub-epigastric veins in passing the sutures. In another case an inguinal varicocele was found under the following circumstances. A youth, aged twenty-one years, who wanted to enlist, had a small reducible hernia of the right side; it was painful and difficult to manage. Upon the left side he had a decided impulse and a bulging of the inguinal canal. We could not, however, satisfy ourselves that he had a rupture there, and the question was discussed as to whether an operation ought to be performed on that side. I decided, however, to explore the canal, first because it is, in my opinion, such a harmless proceeding, and next because I feared to overlook a hernial sac or lipoma or varicocele. On the right side, where we had diagnosed a small reducible hernia a hernial sac was found together with considerable varix of the spermatic veins. As soon as the left inguinal canal was opened a huge bunch of varicose veins bulged out. They looked exactly like a big varicocele in the wrong place. It was quite obvious that they were actually distending the inguinal canal. No hernial sac was discovered. The veins were clamped above and below; excised, and the ends tied with a Staffordshire knot. The patient made an uneventful recovery. Now it is quite clear that had this canal not been opened our doubt would have continued, he might have been rejected for the army, and someone might ultimately have ordered a truss. In another case an inguinal varix was met with in the right inguinal canal of a young man. When he coughed or strained, the inguinal canal being open, the veins swelled up and bulged in an extraordinary manner. It is not unlikely but that varix of the veins of the cord may by distending the inguinal canal and preventing its valve action have some relationship to the causation of inguinal hernia. For instance, another youth was operated upon for the cure of a right epiplocele; a large varix of the cord was likewise found, and whenever he coughed or strained during the operation the veins filled with blood and became so huge that they seemed well calculated not only to distend the inguinal canal but also to prevent its closure during the

Digitized by Google

muscular contraction. Varix of the cord was treated in all cases by tying the veins close to the peritoneum above and outside the external abdominal ring below, cutting away the intervening portion. Whenever possible the ligatures were made to transfix the pedicle lest they should slip off. Care was also taken to leave one or two of the healthier-looking veins in order to provide for the return of blood. This operation is performed through the usual inguinal incision made half an inch above, and parallel to, the inner half of Poupart's ligament. It is usually about three inches long. So far no case of atrophy of the testis has been met with in the cases in which these varicose veins have been taken away, nor has the operation ever caused orchitis. Inasmuch as some of the more conservative school of surgeons apply trusses to all who complain of pain about the inguinal canal accompanied with impulse, it is clear that a good many individuals are going about wearing trusses upon inguinal varicoceles or upon fatty tumours of the cord. Perhaps I should add that in women the veins of the round ligament of the uterus are sometimes enlarged in a similar way and may bulge the inguinal canal so as to simulate a hernia.

Having been at special pains to watch the after progress of cases in which the inguinal canal has been opened I do not remember to have met with one in which the aponeurosis of the external oblique muscle has failed to unite again. Indeed a little consideration leads one to suppose that such a failure is not very likely to occur. The aponeurotic fibres are arranged parallel to each other, so that whenever they are pulled upon they merely tend to approximate. In the operation they are split and pulled apart and on no account cut across. Hence it is that I do not hesitate myself to explore the inguinal canal under circumstances in which it has hitherto not been the custom among surgeons to do so, and unhesitatingly follow the spermatic cord into it in case of tubercle of the testicle or of malignant disease. Hitherto very little attention has been given to the subject of inguinal varix or varicocele. I myself should have been unconscious of the existence of such a disease had I not seen it whilst operating. During life an inguinal varix or varicocele is almost certain to be mistaken for a small incomplete inguinal hernia, and after death the veins would, of course, be empty and not at all likely to attract attention. The cases of inguinal varix do not seem to me to be quite alike. In some the veins of the spermatic cord are merely dilated and more conspicuous than usual. Their walls are thin so that the blood shows easily through, and they adhere closely to the cord and its coverings, and to the hernial sac when one exists; also, although they fill the inguinal canal they do not seem so inclined to crowd out when the aponeurosis of the external oblique is cut. Indeed, their presence is not always very obvious until the later stages of the operation of radical cure, when the sac is being taken away and separated from the cord. But in other cases of inguinal varix more than a mere dilatation of the veins of the spermatic cord and of its coverings is in question. The varicose veins have the closest resemblance to a scrotal varicocele. They push forward in a bunch as soon as the inguinal canal is opened. They are easy to separate and have hypertrophied walls, through which the colour of the blood is not easily seen. It is this last variety which so closely simulates an incomplete inguinal hernia. It is possible that this inguinal varicocele differs in one respect from scrotal varicocele in being found about as often upon the right side as upon the left. However, a great deal more information is needed upon this point.

I now propose to refer to another condition in which I have explored the inguinal canal with interesting results. I always look upon congenital hydrocele of the cord in boys with some suspicion, and now unhesitatingly explore the inguinal canal when curing the hydrocele. A youth, twelve years of age, had a considerable hydrocele, which was opened through a small incision in the upper part of the scrotum; the cyst did not communicate with either the tunica vaginalis or with the abdomen. The cord itself felt very hard, but a probe could only be pushed up it for three-quarters of an inch along a little canal which led from the inside of the hydrocele, but when the inguinal canal was explored a large hernial sac was found. There was no evidence whatever of its presence, but the patient said he thought he had worn a truss when an infant. Doubtless some would have looked upon this as a case cured by a truss, but I have long since arrived at the conclusion that oftentimes such a cure is more apparent than real; not a few suddenly relapse, an event which is easily explained when we consider such cases as that which I have just described. Another youth came with a small tense hydrocele of the cord; it was above the tunica vaginalis and just outside the external abdominal ring. He stated that at times another protrusion appeared above the hydrocele. After a few days in bed the hydrocele disappeared. At the operation its sac was opened and found to have a long and narrow tube leading into the abdomen. The inguinal canal was opened and this tube dissected out and its base transfixed and tied with No. 3 or No. 4 twisted silk close to its junction with the peritoneum. Then if the sac is quite slender the silk is divided and the stump allowed to spring back behind the muscular fibres of the internal oblique and transversalis abdominis muscles. Should the peritoneal canal be large and resemble a hernial sac it is fixed beneath the transversalis muscle and fascia by carrying the ends of the ligatures which transfix and encircle the stump through the abdominal wall at a point above and external to the centre of Poupart's ligament. As a rule in these cases it is unnecessary to put any stitches in the back of the inguinal canal. It is only requisite to suture the aponeurosis of the external oblique muscle with interrupted sutures of fine silk, and so close up the canal again, and finally suture the skin incision.

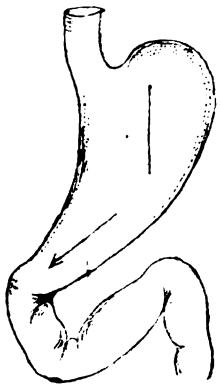
In addition to these cases which I have just described I have operated upon several others of encysted hydrocele of the cord in which a peritoneal canal was found running up the inguinal canal towards the abdomen. It is obvious that had such peritoneal canals or sacs as those which I have just described been left behind in the inguinal canal they would have been in all probability a continual source of danger to the patient. When the intestine descends suddenly into such sacs the symptoms of strangulation are of the most acute and dangerous kind. I have twice at least seen this acutely strangulated intestine become gangrenous within a comparatively short period of time. In one of those cases I was so fortunate as to have a recovery after the removal of the gangrenous intestine with subsequent enterorrhaphy.

Of late years I have treated all cases of encysted hydrocele of the cord by an open incision. In some the hydrocele can be drawn up through the usual incision parallel to the inner half of Poupart's ligament, the scrotum being left untouched. This procedure has the advantage of leaving a wound which is more easy to dress and to which a certain amount of pressure can be applied. Sometimes, however, it is necessary to carry the incision from the inguinal region into the upper part of the scrotum. Then the wound becomes more difficult to dress, and as no real pressure can be applied to it the surgeon should be prepared to put a drainage tube into the scrotal part for the first twenty-four hours to let out any blood. I generally use a scrotal dressing which has an additional prolongation to cover the inguinal region.

I now propose to refer to exploration of the inguinal canal in certain cases of retained testis. About 15 per cent. of the cases of inguinal hernia on which I have operated have been complicated with retained testis. As is well known, the testicle may be arrested during its transition either in the abdomen, in the inguinal canal, or after its exit from the inguinal canal. It is more particularly with the two latter positions that we are at present concerned. It is generally assumed that the exact position of the retained testicle can be easily diagnosed during life, but the results of operations have led me to think that mistakes must not infrequently occur. For instance, a patient was operated upon in whom we all thought that the testicle lay in the inguinal canal, and apparently covered by loose and stretched aponeurosis of the external oblique. When the organ was pressed upon it slipped away from the finger and apparently disappeared within the abdomen. When, however, an incision was made the testicle was not found in the inguinal canal, but lying in a sac upon the aponeurosis of the external oblique exactly over the inguinal canal. This sac had no communication whatever with the abdominal cavity, and the external abdominal ring itself was so small that it was obvious that the testicle could not have entered the inguinal canal, much less the abdomen. Cases in which the testicle has emerged from the inguinal canal and then turned back again to mount upwards upon the aponeurosis of the external oblique are not infrequent, and are particularly favourable, owing to the length of the spermatic cord, for the transplantation of the testicle into its proper place—viz., the scrotum. But when this has been done the question at once arises as to whether the inguinal canal should be let alone

Digitized by Google

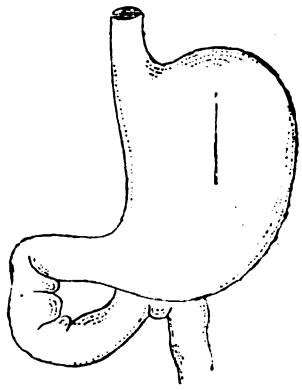
or explored. That the latter is the proper procedure is exemplified by the case I have just mentioned. When the aponeurosis of the external oblique was cut through a small hernial sac was found communicating with the abdomen by rather a wide mouth. It is obvious that had this been overlooked the patient might at some time after the operation been obliged to burden himself with a truss or have a second operation performed for the cure of the rupture. It also leads one to reflect upon those cases of retained testis and hernia in which, as is commonly done, a truss is applied upon the retained testis, which, as is usually said, is supposed "to take care of itself." It seems unscientific and irrational to attribute so much intelligence to an organ like the testicle and to expect it to undertake duties which ought to be performed by the surgeon. When the testicle lies in the inguinal canal it is of course necessary to open the canal to approach the organ, but even here the question of a further operation arises, because unless the upper part of the inguinal canal is carefully explored by a free division of the fibres of the external oblique aponeurosis the hernial sac or a long serous canal may be easily overlooked. In the case of a man both of whose testicles were retained in the inguinal canal I found on the left side that the organ lay in a capacious sac which did not communicate with the abdominal cavity, but a careful search in the inguinal canal behind the upper end of the testicular sac brought to light another sac which communicated with the abdominal cavity and was exactly like the sac of an infantile hernia. In other cases, as I have just said, the testicular sac communicates with the abdomen by a long, slender canal, which might easily be overlooked unless it was diligently searched for with a probe or by exploring the highest part of the inguinal canal. Although it has no direct bearing upon the question of the propriety or otherwise of exploring the inguinal canal, nevertheless, I may, perhaps, be permitted to remark that much remains to be learned concerning the after-progress of cases in which retained testes have been transplanted into the scrotum. It is now well known that these undescended organs do not, so long as they remain in the inguinal canal or in the abdomen, attain their proper development. So far as I can learn no one has yet seen spermatozoa in undescended testes. Whether this applies also to cases in which the organ has left the inguinal canal and then turned back again so as to lie in the aponeurosis of the external oblique I do not know, but in four or five cases of this kind upon which I have myself operated the testicle has certainly appeared larger than those in which it had not left the canal. By this time there must be a good number of cases in which these undescended testes have been transplanted into the scrotum and some of my hearers may meet with them. It is to be hoped that opportunity will be seized of ascertaining as far as possible the condition of the transplanted organs. I have seen at least ten cases at periods varying from six months to two years after the operation. This much seems to be clear, first, that the testis remains in the scrotum, or if it should ascend at all it is sufficiently low down to be quite out of the way of a truss; second, that the organ does not undergo any further diminution in size; third, that, in one case not only has it not diminished but both myself and the patient are of opinion that it is larger than when it was at first transplanted (if this be true it is a very encouraging circumstance); and fourth, although a matter of less importance, nevertheless it is worthy of note that the patients themselves are extremely gratified to find that the organ has been preserved, and when they know this can be done are much more anxious to have an operation performed. To recapitulate, it is clear that without the exploration of the inguinal canal surgeons who may claim to possess ordinary powers of diagnosis may mistake a lipoma for a hernia, varix of the spermatic veins for a hernia, or may overlook peritoneal canals or actual hernial sacs. These are some of the considerations which have led me gradually to abandon operations for the radical cure of hernia in which the interior of the inguinal canal is not clearly seen; moreover, as I have already explained, these are the conditions which have led me to explore the inguinal canal with greater freedom than has hitherto been the custom.



In conclusion, perhaps I ought to say that such operations as these would not be advisable unless the operator takes every pains to attain asepsis. I need hardly detail the precautions which, in my opinion, ought to be taken, but they include the disinfection by heat of all instruments and materials, the thorough disinfection of the skin both of the surgeon and of his assistant and of the patient, and finally the application of a suitable dressing. In conclusion, I will hand you the outside dressing which we find most efficacious and most comfortable in the treatment of these inguinal and scrotal wounds.[1]

A CASE OF PYLORIC STENOSIS TREATED FIRST BY LORETA'S OPERATION AND AFTERWARDS BY POSTERIOR GASTRO-ENTEROSTOMY (DOYEN).

BY JOHN W. TAYLOR, F.R.C.S. ENG.,
SURGEON TO THE BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN, ETC.



BEFORE narrating the case which is the subject of my paper I should like to draw attention to the fresh knowledge which has invariably been the outcome of surgical effort. Every department of medical science has profited more or less by the surgical interference which has been so much a feature of modern practice. It has undoubtedly been the operative treatment of diseases of the uterus and its appendages, of the liver and gall-bladder, of the kidneys and of the brain, which has opened up to all of us much of our present heritage of facts—facts on which we act—facts which form the foundation of a more successful practice. The region of the stomach will, I think, prove no exception to this general experience. So long as the stomach remained unexplored during life men seemed content to accept the diagrams of their anatomical text-books, and not a few of us to-day may perhaps still regard the stomach as a

musculo-membranous sac, the long axis of which lies across the upper part of the abdomen. Clinical examination has often tended to perpetuate this idea. The distended transverse colon, closely applied to the stomach, has been unwittingly accepted as a part of it, and careful palpation and percussion have tended to confirm the error, or attention has been confined to dilated and abnormal conditions of the stomach, and what was altogether pathological has been accepted as differing but slightly from the normal position and relations.

Dr. Doyen, of Rheims, in his work on the Surgical Treatment of Diseases of the Stomach[1] has done much to elucidate and explain these points, and I have reproduced a few of his illustrations because it seems to me that a better appreciation of the normal position of the stomach is necessary before we can begin to understand any of its pathology. The long axis of the normal stomach is very nearly vertical, and when empty the pylorus should be its most dependent part (Fig. 1). The latter should lie only very slightly to the right of the middle line, and the pyloric end of the stomach, the entrance to the pylorus or "antre du pylore" of the French, should be exactly central. A rough generalisation which I have ventured to make at once places the salient features of this normal position clearly before the mind—the alimentary tract from the mouth to immediately above the pylorus is nearly direct, broadly vertical, and almost central. There is a dilatation or pouch on the left side formed by the greater curvature of the stomach, but the tract itself is practically direct from the pharynx to the pylorus. This may be seen very well in the first frozen section plates in Braune's Topographical Anatomy; it may often be verified by careful clinical examination and, to some extent at least, by personal experiment. The act of swallowing anything very hot or very cold may sometimes be experimentally followed by corresponding sensation from the mouth to the pylorus. The central position of the sensation throughout, although not absolutely prohibitive, perhaps, of another direction, forms strong presumptive evidence of the truth of this contention. It is mainly because of this that the lesser curvature and pylorus are immediately affected by irritating foods and caustics and become so frequently the seat of ulceration and disease, while the greater curvature, which used to be regarded as the immediate receptacle of food, escapes. The recognition of this appears to me to throw considerable light on all gastric and pyloric disease; it makes so much that was formerly difficult to understand reasonable and clear that I may be pardoned, I think, for having insisted on its importance before proceeding to the consideration of the case I have to report.

A single man, aged thirty-three years, was sent to me in July, 1894, by Dr. Bernays, of Solihull. The patient had been complaining for four or five years of gastric trouble. Attacks of pain and acid vomiting, lasting for a week or so, had occurred at intervals of some months' duration until the latter part of 1893. At this time the pain increased and occurred daily. The pain was felt in the pit of the stomach, a little above the umbilicus and in the back, and was worse three hours after taking food. About three times a week (towards 2 or 3 o'clock in the morning) he vomited four or five pints of brownish acid fluid which became frothy on standing. After this had continued for some eight weeks he became a patient at the Queen's Hospital, under the care of Dr. Foxwell, who diagnosed the case as one of dilatation of the stomach, and, I believe, admitted him into his wards as an in-patient. During his stay here the patient was treated by washing out of the stomach, and from this he derived very considerable benefit. On leaving the hospital he had increased in weight 2 lb., and being a very intelligent patient he was able to continue the washing out of the stomach himself. For a time the improvement continued and appeared to be very materially assisted by a course of medicine and dieting ordered for the patient by Dr. Bernays, who now had charge of the case. The improvement, however, did not last, and before I saw the patient he had been rapidly getting worse. He had to use the stomach tube twice a day in order to get any relief from pain, and had lost 20 lb. in weight during the month preceding my consultation. Latterly Dr. Bernays had ordered nutrient enemata, as very little or nothing appeared to be retained by the stomach. Dr. Bernays sent the patient to me, hoping that something further might be done by surgical means. When I saw the patient on July 20th I found him very emaciated and weak. His rectum was nearly empty in spite of marked and continued constipation. His pulse was quick and rather feeble (108), and palpation and percussion of the abdomen showed very decided signs of dilatation of the stomach, the stomach resonance being increased in all directions and splashing marked on gentle bimanual examination. No tumour could be felt nor could I find evidence of any other disease. A week later (July 28th) I operated. I opened the abdomen in the middle line between the ensiform cartilage and the umbilicus. The stomach was dilated and appeared immediately under the incision, the vessels along the greater curvature looking large and injected. At the pyloric end of the stomach there was very considerable thickening of its walls. In this situation the thickening was "patchy," and wherever it was found it was noticed that the peritoneal coat looked whiter and rather lacking in lustre. Further down, at the pylorus itself, the thickening was general and there appeared to be some folding adhesions of the peritoneal coat. On taking up a fold of the stomach wall over the thickened region the increased substance between the fingers—amounting to several lines—was very perceptible, but nowhere did it amount to anything that could be termed a tumour, and the change appeared to be partly fibrous, very largely inflammatory, and not malignant. I opened the stomach just above the pylorus. The latter seemed to be quite occluded save for a dimple in the mucous membrane which would barely admit a uterine sound. I gradually dilated the pylorus with Sloan's dilators, at first with considerable difficulty. Then it suddenly gave (I believe by the opening out of external fold adhesions, as no rupture could be found), and from this point the dilatation proceeded rapidly until I could pass my forefinger through the pylorus. The mucous membrane of the stomach, pylorus, and duodenum felt healthy. I could find no evidence of ulceration, old or recent, and the changes already noticed appeared to be confined to the serous and subserous tissues. No definite ring of constriction was found at the pylorus, but rather a tubular narrowing for some distance, and a pyloroplastic operation which I had had some intention of performing I found to be hardly applicable to my case. I dilated the pylorus still further by means of Goodell's strong dilator, with parallel blades, until I judged that the limit of safe distension had been reached. In this case the operative dilatation of the pylorus was not carried so far as in some of the reported cases. I could not pass two fingers through the pylorus, but could easily pass the index finger beyond the second knuckle. On bi-digital examination from within and without the intestine it seemed to me that any further stretching must result in rupture; indeed, at this stage something occurred which felt like a little crack in the posterior wall, and I judged it best to desist from any more manipulation. I closed the wound in the stomach with a continuous Lembert suture—that is, a running suture passed in exactly the same way as an interrupted Lembert suture. I have always used this for any intestinal work and am quite satisfied with it. I began the suture a little beyond one end of the incision and after uniting the sides of the incision (taking up serous and muscular coats only) continued it for a similar distance beyond the other end. I then returned, using the same thread, by a similar suture above the first one, and finished the operation by tying the ends of the silk together. The abdominal incision was closed with silkworm gut. The operation lasted an hour. Before I began the patient had himself washed out his stomach, and there was very little leakage from the stomach wound. The latter was carefully guarded by the fingers of my assistant, Mr. Jordan. The patient was fed by nutrient enemata or nutrient suppositories until Aug. 2nd—that is, for five days. After this milk and gruel were given by the mouth, and by Aug. 12th the patient was allowed a very fair dietary of egg, fish, brown bread, and cocoa, in addition to the milk. He left the nursing home on Aug. 16th, his weight being 8 st. 6 lb., or 1 lb. less than at my first consultation.

I have weekly records of his weight since this date, and with but few exceptions there has been a slow and steady increase. The last weight recorded (Feb. 26th, 1895) is 10 st. 6 lb. or almost exactly 2 stones heavier than at the time of operation. With this increase of weight there has been a corresponding improvement in other respects. The patient is much stronger and able to do some work; his appetite is good, and although occasionally subject to some indigestion and

Digitized by Google

gastric pain he has never had to use the stomach tube since the operation, and has only been sick about six times since he left the hospital. On examination I think it may be said that although there is marked improvement some signs of dilatation still remain, and on palpation a certain amount of splashing is still usually present. Whether the maximum of improvement has been attained is very doubtful, considering that the highest point of weight was touched so recently. The very gradual and steady change for the better, extending over seven months now, seems certainly ground for hope that the improvement may still continue.

Remarks.—A case of non-malignant stricture of the pylorus, verified during life, affords a special opportunity for study, and I have tried to find, if possible, what cause or causes may have led to the condition found. The patient had always lived in the country, and his usual occupation was that of a gardener or farm labourer. He came of a fairly healthy stock and had no vices. He had no history pointing to any gastric ulcer in the past, no acute history, either of hæmatemesis or otherwise, previously to this closure of the pylorus. He had never been intemperate, had rarely taken spirits, and when he had these had always been diluted. He had never chewed tobacco, but had been a great smoker. So far the history seemed to be an innocent one. But he had always had the character of being a very quick eater—of finishing his meals before other people; and this, when the fare was rough, and but little or no rest could be taken after food, might perhaps be an etiological factor of some importance. The more recent Continental writers (Reichmann and A. Robin) appear to trace this form of pyloric contraction to a hypersthenic dyspepsia in which there is a definite increased secretion of hydrochloric acid, and I notice that Doyen constantly refers to this "hyperchlorhydrie" or "maladie de Reichmann" as a cause of simple pyloric stenosis. Ewald, although treating this hyper-secretion of gastric juice as a functional neurosis only, remarks that "the irritation excited by the acid fluid leads to troubles having the appearance of the symptoms of a chronic inflammatory condition," and, further, "in consequence of this condition atony of the muscular coat and dilatation of the stomach may occur; this is so common in cases of long standing that out of thirty cases in Reigel's wards in twenty-nine there was more or less distinct dilatation."[2] That the acid vomiting so frequently met with from the earliest stages of gastric dilatation is not entirely due to acids of decomposition, but to a true hyper-secretion of acid appears to be now well established, and contraction of the pylorus is very frequently associated with long-continued hyper-secretion of hydrochloric acid, but the chain of cause and effect, if it exist at all, has not as yet been made out, and it appears to me that there must either be a pre-dyspeptic stage which starts the hyper-secretion, or some contemporaneous cause coöperates with the acidity in producing so marked a local manifestation and lesion.

In the case described above the local disease was marked and definite—a peri-pyloric inflammation not dependent on ulcer or extraneous causes, involving the pyloric end of the stomach only and causing local thickening and adhesions. In the history the rapid eating or bolting of the food was the only discoverable cause of irritation. Is it not possible that coarse and imperfectly masticated food passing (more directly than has been supposed) into the pyloric end of the stomach may irritate and at once be seized by the closing action of the pyloric region and for a time at least be kept from participating in those rhythmic movements of the stomach which facilitate digestion? This would excite an increased secretion of hydrochloric acid which, at first intermittent, would gradually become chronic; irritable fissures would easily occur in the neighbourhood of the pylorus, and in this way it is easy to understand how a chronic inflammatory process might arise that would gradually lead to pyloric contraction and finally to closure.

I feel that my own knowledge of the literature of the subject is too imperfect and my experience too small to warrant anything but a tentative suggestion as to the primary causation of non-ulcerative pyloric stenosis. I cannot but believe that so local a disease must have a local cause, and if the history I have been able to elicit is only of value on the negative side of the problem it may still help to clear the ground for further work.

Three operations have been proposed and employed for the treatment of non-malignant stricture of the pylorus—pyloroplasty, Loreta's operation of digital dilatation, and gastro-enterostomy. Pyloroplasty is specially applicable to a sharp, annular constriction, and consists of a longitudinal incision through the stricture followed by transverse suture of the wound. In suitable cases it seems to be an exceedingly neat and useful operation. When the site of constriction is almost linear the operation is an ideal one and should be followed, if successful, by a permanent result. But the field for its use is, I think, much more restricted than many have supposed, and in my own case I had to choose between dilatation or gastro-enterostomy.

Dr. Doyen, whose experience of the latter operation has been remarkably extensive and successful (twenty-one cases with five deaths), has practically given up both pyloroplasty and Loreta's operation in favour of his own method of gastro-enterostomy, and it may be that with increased experience of gastric surgery other surgeons will tend to follow his example. I certainly think his method of operating is much superior to the plans which have hitherto been used, and I would employ Doyen's operation in preference to any other for an early case of cancer of the pylorus.

The objection which has been felt to Loreta's operation and which runs through all the theoretical literature of the subject is the danger of relapse. But theory must be tested by experiment, and after considerable search I cannot find any clear record of relapse in the cases which have been published. On the contrary, there is considerable evidence to show that at intervals varying from several months to one or even two years the benefit obtained by Loreta's operation has been thoroughly maintained. The first two cases operated on by the late Professor Loreta were said to be doing well by Dr. Guido Pedrazzoli ten months after the date of operation.[3] Mr. Hagyard's case was reported as perfectly well nearly two years after operation,[4] and Mr. Treves's case, operated on on Dec. 3rd, 1887, was quite well in December, 1888.[5]

Sequel.—The foregoing account was written in 1895, and the improvement then recorded was maintained during the whole of that year. Early in 1896 symptoms of relapse first showed themselves. Pain and vomiting again set in and the patient again lost weight. I did not see him until May, 1896, his weight then being 9 st. 5 lb. By washing out the stomach once a day he managed to keep about this level for some months, but as all the old symptoms returned—decomposition of the gastric contents, periodical vomiting, and nocturnal pain—it was evident that something more was needed, and I accordingly suggested the formation of a new pylorus towards the most dependent part of the stomach as likely to give fuller and more permanent relief. My intention at this time was to operate by the method of anterior gastro-enterostomy recommended by Dr. Doyen in his book on the surgery of the stomach; but on talking over the matter with Dr. Doyen, both at Rheims and in London, I found that he had practically given up the anterior method, and in his more recent gastro-enterostomies had united the jejunum to the posterior wall of the stomach. His main reason for this change was, if I understood him correctly, that in some of his cases where he had united the first part of the jejunum to the anterior wall of a much-dilated stomach on the lying down of the patient the (dilated) posterior wall "sagged" or pouched into a depending cavity in which the food still collected, decomposing and causing continued gastric trouble, although in every other respect the operation was satisfactory. The objection seemed to me to be a reasonable one, and as I knew that my patient's stomach was much dilated, and found that on the cadaver it seemed to be almost as easy to use one wall as another for the site of anastomosis, I did not hesitate to choose posterior gastro-enterostomy as the better operation. I did this for my patient on Sept. 12th, 1896. I reopened the abdomen in the line of the old incision and found the pylorus and pyloric end of the stomach so universally involved in firm adhesions that I did not trouble to disturb them in order to examine more minutely into the present condition of the pylorus. Pushing up the stomach and great omentum, I passed my fingers deeply into the abdomen, felt for the ligament of Treitz, which marks the end of the duodenum, and immediately pulled up the first part of the jejunum. In the mesentery of this, nearly to its fixed extremity, I passed a double thread

Digitized by Google

of silk for future identification of the loop of jejunum. Then, dropping this into the abdomen, I drew out the great omentum, which in this patient showed no sign of the transverse colon on its anterior aspect. This was held up for me by my assistant, Mr. Jordan, and tearing a hole in its under layer anterior to the transverse colon I came at once on the posterior wall of the stomach. This and the loop of jejunum to which the silk had been attached were now drawn outside the wound, all other exposed abdominal contents were replaced, and the loop of jejunum being disposed from left to right in easy relation to the posterior gastric wall was held in position by Mr. Jordan while I began to join the bowel and stomach by suture. Up to this point I cannot say whether I exactly followed the method of Dr. Doyen or not, as my conversation with him on the subject was hurried and imperfect; but in all the main details of the formation of the ostium and union between the stomach and the bowel I followed the direction in Dr. Doyen's book. These are, briefly, as follows. A somewhat crescentic line of suture, about four inches in length ($a - a$, $a' - a'$), is made with the finest silk to form the

FIG. 4.

Diagrammatic sketch of posterior wall of stomach and jejunum, showing lines of sutures and openings into both viscera.

deepest, or highest, line of union between the convexity of the bowel and wall of the stomach; within, and more or less parallel with this, a second line of suture, about three inches long, is carried ($b - b$, $b' - b'$), the two together forming a broad concave band of union between the two organs. In the hollow of this concavity the openings, about one inch long, are made into the stomach and jejunum, the incisions being united to each other by a very fine continuous circular suture through all the coats, the end being tied to the end when the union is completed so that one fine silk thread unites the whole of the circle without a break ($c - c$, $c' - c'$). While this is being done the stomach and bowel are temporarily clamped to avoid unnecessary soiling of the wound. As soon as the circular suture of the anastomosis or "ostium" is completed the clamps are removed and any stomach contents are allowed to pass into the small intestine by the new opening. (At this stage the junction between the stomach and the bowel is formed by the union of a pouting mouth or ostium on both sides, so that from above it looks as if both viscera were joined by a short intestinal tube.) If the union appears to be quite satisfactory the parts are carefully cleansed, and the circular suture is buried or closed in by a somewhat curved line of suture uniting the ends of the second concave line of suture ($b \ldots b$, $b' \ldots b'$), and finally, by a similar suture joining the ends of the first line of suture ($a \ldots a$, $a' \ldots a'$). In doing this by simply carrying the suture of the jejunum relatively wider on the gastric or upper side a valve or spur may be formed which, while causing no obstruction to the passage of the glandular excretions, prevents any back flow from the stomach. The gastro-intestinal opening is now not only formed and protected all round by an immediate circular suture, but there are two complete (crescentic) rings of suture outside this. The anastomosis is complete, and after replacing the parts within the abdomen and closing the abdominal incision the patient is put back to bed.

The operation lasted about two hours. Beyond the tediousness of it, and the profound anæsthesia induced, from which the patient did not recover for three hours afterwards, the operation does not call for any special notice. From the date of it all vomiting ceased and has not since recurred. I only allowed the patient to have a little milk by the mouth for the first three days, and so long as solid food was denied him he complained somewhat bitterly of pain and restlessness. As soon as he was permitted to take solid food the pain disappeared and his recovery was rapid and uninterrupted. He has regained his usual weight and has remained in excellent health ever since. On inquiry of his medical attendant, Dr. Bernays, I find that he remains to the present day, "perfectly well and is able to eat anything" (Oct. 19th, 1897). The last time I saw him I was interested to notice that there was less evidence of any dilatation of the stomach than at any period since I had known him, and it appeared to me that the organ was recovering, to some extent at least, its normal size and elasticity.

Birmingham.

VITALITY.[1]

BY LIONEL S. BEALE, M.B., F.R.C.P. LOND., F.R.S.,
EMERITUS PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN KING'S COLLEGE, LONDON, AND CONSULTING PHYSICIAN TO THE HOSPITAL; GOVERNMENT MEDICAL REFEREE FOR ENGLAND.

IX.—THE INTERSTITIAL CIRCULATION IN ALL LIVING THINGS (*continued*).

WHETHER the interstitial fluid which circulates in the bioplasm and in the various tissues is derived from the circulating fluid within the organism, as in man and the higher animals, or from the surrounding medium, as in the case of the lowest organisms, the distribution is never equable in all parts of the organism at the same time. In man and the higher animals the supply will be affected by the variation from time to time in the calibre of the vessels which distribute it to the part, and will vary according to the periods of repose and activity. The change in the calibre of the arterioles is effected by a marvellous arrangement which acts automatically. Thus the varying local blood-supply is mainly dependent upon the varying degree of contraction of the muscular fibres encircling the vessels, which is determined by changes in the nerve current effected in the nerve centres, from which the nerves distributed to the arteries emanate. I have done my best to describe and illustrate the arrangement, which is of great interest, in previous memoirs and works.[2]

The bioplasm of those tissues and organs which are necessary to the life of the organism from moment to moment requires a larger proportion of nutrient matter in a given time than the living matter of those which are not constantly in a highly active state. Of the rest some have pretty regular periods of activity and rest, but at all ages the parts which are undergoing renovation are supplied, not only with plenty of interstitial fluid, but very free interchange and admixture of the currents of fluid takes place, so that neither the nutrient matters nor the products of disintegration should form a strong solution. In any given tissue of an animal at different ages there is what may be called a normal rate of vital action of any particular form of bioplasm, and a normal rate at which the conversion of a portion of the bioplasm into formed material takes place, as well as a normal rate at which the interstitial fluid flows to and from the bioplasm. But normal activity varies within certain limits in different organisms and at different ages, and in the same organism at different times under different conditions and in different parts. Living too quickly or too slowly tends to be detrimental, whether the departure from the normal rate affects a minute amount of bioplasm or that of a considerable part or the whole of an organism. A slight departure, however, in either direction from the normal may

[1] Nos. I., II., III., IV., V., VI., VII., and VIII. were published in THE LANCET of Feb. 22nd, April 11th, June 13th, Aug. 29th, Oct. 17th, 1896, Jan. 23rd, July 31st, and Sept. 4th, 1897, respectively.

Digitized by Google

occur without detriment. Indeed, throughout all living nature these several processes are permitted to vary within moderate range and may be automatically corrected, but neither can proceed far from the normal standard of change without derangement or actual damage; and if the divergence persists for longer than a short period of time serious structural and other events follow. Physiological may soon be replaced by pathological phenomena. *The too rapid growth and multiplication of the bioplasts, the too quick production of formed material*, are serious departures from the healthy state, and are changes which as it were lie at the root of many morbid processes. Health as well as longevity seems to depend upon the steady maintenance of the normal changes in the bioplasm of certain parts of the organism at the several periods of life.

Should the interstitial fluid become too concentrated, as it does in some departures from the normal state, it might flow too slowly through the tissues for normal nutrition; or by the undue accumulation in it of matters which ought to be quickly removed there is danger of the deposition of certain substances in the tissue, in which case the action of the latter may be seriously interfered with or checked. In some cases the fluid accumulates interstitially to an extent sufficient to cause visible swelling of the tissues in the neighbourhood, and the increased amount of too rapid growth is followed by multiplication of the bioplasts. This undue accumulation of interstitial fluid is not confined to textures near capillary vessels, but occurs also in those which are separated from the capillaries by a considerable thickness of tissue, as in some forms of cartilage and in many epithelial textures. The change in question may occur very rapidly, but may be followed by the deposit of lymph and the formation of fibres, in which case a considerable time must elapse before the fluid poured out is completely reabsorbed and the deposited matter dissolved so that the tissue may regain its normal state. Indeed, to effect this it is necessary that the interstitial fluid should be in a state of dilution for a long period of time.

The importance of the free interchange of the interstitial fluid and the thorough and continued admixture of its constituents cannot be over-rated, and by the great number, constant movement, excessive minuteness, and varied direction of each little stream this admixture is in the normal condition undoubtedly ensured. In the case of the blood-streams, large and small, thorough admixture of the several constituents of the constantly circulating fluid upon a much larger scale is effected by a special arrangement which cannot but be regarded with great interest, and by which several other conditions of the greatest importance in the physiology of the higher animals and man are fulfilled. The red blood corpuscles, in addition to other offices performed by them, are intimately concerned in the admixture of every portion of blood, so that in the normal condition danger from the accumulation of various substances of a deleterious character is reduced to a minimum. These corpuscles are always changing their relative positions with respect to one another, and in the web of the foot of the young frog the soft flattened discs may be seen continually sliding over one another as the blood is propelled through the capillaries. By no other means could such thorough admixture of the dissolved constituents be so certainly ensured in a considerable body of fluid.

In every part, then, of all living organisms, present and past, and at all periods of life, in and around each little bioplast flow very minute streams in constant motion, some bringing nutrient substances to the living matter, while others take away from it and from the adjacent tissue, matters not adapted for nutrition and products which have resulted in the course of oxidation and disintegration. These streams never cease to flow as long as life lasts. In the case of some fully formed hard textures, such as bone and some vegetable tissues, all the streams are restricted to certain defined channels, but even under these circumstances there is free admixture of the portions of the interstitial fluid, and until the tissue is fully formed there is room for several different streams in the space which at length is to become a narrow canal.[3] In every tissue and organ there are multitudes of streams of interstitial fluid, most of which are probably much less than the one-hundred-thousandth of an inch in diameter, passing to and from the particles of bioplasm, moistening, irrigating, cleansing, and preserving the intervening tissue and other kinds of formed material, and at the same time supplying the bioplasm with everything necessary for its life. Thus every part of the body is kept in a state of healthy activity.

There is another point with reference to the nature and influence of the interstitial fluid which it is well to touch upon. Just as we find multitudes of colourless particles of bioplasm in the blood, so very small that they cannot be demonstrated without great care, so, freely moving in the interstitial fluid are also minute particles probably of similar nature.[4] These, like all other known forms of living matter, take up nutrient material from the surrounding medium and grow; and in certain conditions under which there is much interstitial fluid, increase considerably in size, so that they are to be demonstrated without any difficulty. Such very minute particles of bioplasm easily pass in either direction through the walls of capillary or lymphatic vessels. Whether found in the blood, lymph, or other fluids in serous cavities or in interspaces amongst the tissues, these minute particles of living matter take up any excess of nutrient substances that may be in solution and grow at their expense and, as already stated, also remove certain products of disintegration that may be present, thereby preventing the formation of deposits of various substances in the interstices of tissues, using up and greatly economising nutrient material, and converting it into living matter destined to undergo further changes into substances capable of being assimilated or eliminated directly or in a circuitous manner. This is one of many methods by which steady and uniform vital action is preserved, notwithstanding constant changes tending to disturb the balance.

From some of my remarks it might perhaps be inferred that the streams of fluid constantly flowing to and from the living matter through the moist surrounding formed material or through the fluid medium in which the organism lived, alternated with one another, or that the inward flowing streams were limited to certain paths and the outward flowing ones to others. But the frequent change in the situation of the current as seen in many plant cells render it more probable in my opinion that the streams are not even momentarily restricted either as regards direction or situation. Perhaps these minute streams may be compared with constantly changing fluid columns, the core of which flows in a direction the opposite of that taken by the circumferential portion. That in certain cases the inflowing stream passes very quickly through the surrounding formed material to reach the living matter seems to me certain, because a few seconds suffice for an alkaline coloured fluid to traverse the outer part of certain cells removed very soon after death and for the colouring matter to reach and be precipitated (?) and retained in the living matter and the nucleus or nuclei in the central part, while the outer portion (formed material) just traversed by the coloured fluid remains colourless.

Whichever way the streams of fluid may be flowing they are seldom straight or symmetrical or regular as regards the distance by which they are separated from one another. As in many other cases in living nature, the shortest, straightest and most direct route is not taken by fibres, tubes, vessels, and many cord-like textures. The currents of interstitial fluid hardly ever flow in straight lines. The same remark may be made with respect to the indications left of the course of the interstitial fluid in the tissues of fossil remains. We find the same general arrangement in the highest and lowest living organisms, whether now existing or in past time. Even the nerves do not pursue the shortest and most direct course from centre to periphery, and sometimes their course is most circuitous.

(To be continued.)

[3] In the formation of bone and many hard textures impregnated with calcareous and other mineral substances a soft formed material is first of all produced around the bioplasm, and this becomes the seat of deposition of the particles upon which the future hardness depends. Gradually the spaces between the points of deposition are encroached upon and become canals irregularly converging towards the particle of bioplasm. The bioplasm itself gradually lessens as the diameter of the channels becomes reduced, and at last is reduced to a small particle, which ultimately dies, leaving a *lacuna* or space with communicating tubes, *canaliculi*, which pass outwards to the circumference of what was once the outer part of the so-called cell. When the bone becomes dry, and often before, the lacunæ and canaliculi become filled with air, and, as is well known, this renders their arrangement so distinct in dried sections.

[4] It is probable that bacteria-germs find their way into the interstices suspended in the streams of interstitial fluid. Even fully-formed bacteria and larger organisms suspended in fluid easily pass through the walls of vessels and reach the interspaces between the elementary parts of tissues.

NOTE UPON A FORM OF ACUTE INFLAMMATION OF THE CONJUNCTIVA ASSOCIATED WITH PUS COCCI.

By SYDNEY STEPHENSON, M.B. EDIN.,
OPHTHALMIC SURGEON TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, ETC.

IN children one now and then observes an acute inflammation of the conjunctiva along with a pustular eruption of the face or scalp, especially when in the form of eczema impetiginoides.[1] It is thought that in these cases the conunctiva has been inoculated by the contents of the pustules upon the skin, which are known to include staphylococci. The transference of contagious particles is brought about, as a rule, by the fingers of the patient, although in other instances purulent matter may run directly into the eye. I have examined bacteriologically several cases of this kind, and in all have succeeded in finding pyococci in the secretion from the inflamed conjunctiva. I am therefore inclined to think that the organisms named may, with fair probability, be looked upon as causing the conjunctivitis. The following case is so typical of the entire series that it may serve to illustrate certain points with regard to diagnosis and treatment.

A female child, two years of age, was brought to the ophthalmic department of the North-Eastern Hospital for Children on Sept. 15th, 1897. The history was that a fortnight before "some yellow humory heads" came out on the skin below the eyelids, especially on the left side of the face. Upon inquiry it was found that an elder sister had lately recovered from a similar eruption affecting the chin and mouth, probably impetiginous in nature. The patient's left eye had been inflamed for seven days. With the exception of measles six months before coming under notice she had suffered no illness of any moment, and her eyes had been well in the interval. On examining the inflamed eye a considerable collection of yellowish-white discharge was seen in the lacus lacrymalis and the conjunctival sinuses. The lids were glossy and swollen, but not in the least tense; the eyeball was reddened; upon the upper and lower palpebral conjunctiva was a thin, greyish membrane, which could be readily detached, leaving the underlying tissues red and thick, with a slight tendency to bleed in a few scattered points. The cornea was bright and clear. The preauricular gland was not enlarged. The temperature of the patient was not raised; constitutional symptoms appeared to be absent. A few scabs were noticed upon the skin below the left lower eyelid. No discharge was present from the genitalia; there was no affection, as swelling or pain, of the joints. There was a negative history of sore-throat both as regards the child herself and those about her.

The diagnosis seemed to lie between an acute inflammation of the conjunctiva due to (1) Klebs-Löffler bacilli; (2) gonococci; (3) Weeks's bacilli; (4) Fraenkel's pneumococci; or (5) pyococci. From a clinical standpoint diphtheritis appeared to be excluded, since the eyelids could be separated without difficulty, the false membrane was easily detachable, the cornea was intact, the preauricular gland was not involved, there were no diphtheritic patches about the skin of the face, and constitutional symptoms were absent. Against purulent ophthalmia due to gonococci were the negative facts that the lids were not tense, that the secretion was not pus-like, that chemosis was not present, and, lastly, that discharge from the vulva or vagina was not present, as is apt to be the case among little girls. The unilateral character of the inflammation, although rather suggestive of pneumococcus infection, could not be regarded as telling much in any direction. Diagnosis, therefore, appeared to be narrowed down to an inflammation produced by Weeks's bacilli of catarrhal ophthalmia, by pneumococci, or by pus-organisms. The probability was that the micro-parasites last-named lay at the root of the mischief.

In order to determine this point a cover-glass preparation was made by lightly smearing a morsel of detached membrane over a glass slip, which was then stained in the usual way. The specimen, when examined with a one-twelfth oil immersion lens, showed merely a few scattered diplococci and cocci, lying upon and between the multinucleated and other cells contained in the preparation. These were found to retain their colour when treated according to Gram's method. This simple experiment was enough to yield valuable practical results, for in the first place it showed that diphtheria bacilli and Weeks's bacilli were absent; and secondly, that the organisms contained in the specimen must be either ordinary pus cocci or pneumococci, inasmuch as gonococci, as is well known, are decolourised by the alcohol employed in Gram's method. With a view to further identifying the organism or organisms known to be present two sloped agar-agar tubes were smeared with a morsel of membrane detached from the conjunctiva and then placed in the incubator at 37·5° C. Two days later each tube showed more or less discrete colonies of two kinds: (1) circular discs of orange hue from 1 to 3 mm. in diameter; and (2) discs looking not unlike dabs of white oil paint from 0·25 to 2 mm. in diameter. From each kind of colony cover-glass preparations were made, some being stained with weak carbolic-fuchsin and others by Gram's method. The colonies in all instances were found to consist of clustered cocci. Accordingly, the presumption was that one was dealing with the staphylococcus pyogenes aureus and albus—that is to say, with the organisms commonly found in styes, boils, carbuncles, and many other of the circumscribed suppurations. As a further proof, some of the water that had condensed in the original agar tubes was distributed in the usual way through three tubes of liquefied peptone-gelatin (10 per cent.), the contents of which were then poured into a similar number of flat-bottomed flasks like those used for the cultivation of bacteria in water. Colonies made their appearance within two days as minute masses visible to the naked eye. After five days' growth some of the colonies were observed to be white and others yellow in colour, while all the superficial ones lay, as it were, in little pits upon the gelatin plate. Later, the medium became liquefied more appreciably around individual colonies, which were found microscopically to respond to the well-known morphological and staining reactions of staphylococcus pyogenes albus and aureus.

As to treatment, a solution of silver nitrate, containing ten grains to the ounce, was applied to the everted conjunctiva of the inflamed eye every other day, and a wash of perchloride of mercury (1 to 5000) used frequently. After ten applications of the silver there was scarcely any discharge from the conjunctiva, which was free from membrane, smooth, and but little swollen. The remedy was therefore discontinued. Upon Oct. 13th the palpebral conjunctiva showed no obvious signs of disease, although some blepharitis, such as often follows an acute inflammation of the conjunctiva, was present. This was treated in the usual way, and the patient was discharged cured on Oct. 27th.

As already stated, the above is typical of several cases in which I have found the two organisms named. This constant association of particular bacteria with a particular clinical type of conjunctivitis tends to indicate that the latter is caused by the former. In further support of this view the fact may be mentioned that upon two occasions I have seen an acute inflammation of the conjunctiva associated with otorrhœa, pus-organisms being present in the discharge both from the ear and from the eye.

ON THE FLAGELLATED FORM OF THE MALARIAL PARASITE.

By W. G. MACCALLUM, M.D.,
JOHNS HOPKINS HOSPITAL, BALTIMORE.

MUCH attention has of late been devoted to the flagellated forms of the malarial organism, and many theories as to its significance have been put forward, none of which have met with general credence. These—the theories of Laveran, Danilewsky, Mannaberg, Manson, Sakharoff, and the Italian school—are too well known to require repetition here. My own observations on these forms as seen in the blood of crows, which are very generally infected with the halteridium of Labbé, have led me to quite different conclusions, and are briefly as follows.

Frequently in slides of the blood of infected crows there appear, after standing from twenty to thirty minutes, elongated motile forms such as were described by Danilewsky as vermiculi in his "Parasitologie Comparée du Sang"; and

Digitized by Google

in order to trace their origin it is necessary to observe closely the changes in the other forms seen in the same blood. Only the mature forms of the organism are seen to undergo any changes in the fresh slide of blood, the half-grown and younger forms remaining unchanged for a long time. The mature forms become rounded off, and are extruded from the corpuscle, which remains as a shadow lying in the plasma.

Both in the fresh and in the stained specimens of blood there can be seen differences which sharply distinguish two forms of the organisms. The forms are identical in outline, but the protoplasm of one is granular and opaque as compared with the clear hyaline protoplasm of the other. This distinction is well brought out in the stained specimen, in which the hyaline form remains almost entirely unstained, while the other takes on a well-marked blue stain with methylene blue. Of these it can be determined that the hyaline forms alone become flagellated.

These two forms, then, become extruded alike from the corpuscle and lie free in the plasma, but generally only a very short time elapses before the hyaline forms become flagellated, according to the process so often and so accurately described by workers on malaria. The granular forms lie quiet beside the nuclei and shadows of the red blood corpuscles which lately contained them, but are soon seen to be approached by the flagella which, having torn themselves away from the hyaline organism from whose protoplasm they were formed, struggle about among the corpuscles. These flagella, which so concentrate their protoplasm as to form a head, swarm about the granular spheres, and one of them plunges its head into the sphere and finally wriggles its whole body into that organism. Immediately on the entrance of this flagellum it seems to become impossible that another should enter, for they may be watched circling about, vainly beating their heads against the organism. The flagellum which has entered continues its activity for a few moments and the pigment of the organism is violently churned up. Soon it becomes quiet again, and remains so for from fifteen to twenty minutes, when a conical process begins to appear at one side of the organism, the pigment collecting mainly to the opposite side. This process grows larger and the pigment becomes more and more condensed until finally we have a fusiform organism with a small spherical appendage crowded with pigment at one end. The other end is hyaline, and the pigment granules which are not crowded into the small appendage are distributed superficially over the posterior part of the body. This spindle-shaped organism moves forward with a gliding motion, sometimes turning at the same time on its long axis, sometimes going through amœboid contortions. Red corpuscles lying in its path are either punctured by the hyaline anterior end, so that the hæmoglobin is allowed to escape into the plasma, or passed over and dragged along by the adhering posterior extremity.

In an intense infection a great destruction of corpuscles occurs; thus in a fresh slide after standing some time even leucocytes may fall victims to the destructive force of these organisms which have been seen to dash through them, scattering the granules into the plasma. As to the ultimate fate and true significance of these forms nothing definite can as yet be stated. In the slide they keep in motion for a long time but finally quiet down and disintegrate. The idea suggests itself from their great power of penetration that they may be the resistant forms that escape from the body during life into the external world. The whole process described above seems to be a sexual process analogous to the sexual process seen in the lower animals and plants which occurs under unfavourable conditions and results in the formation of a resistant "spore."

Recently I have examined the blood of a woman suffering from an infection with the æstivo-autumnal type of organism in which a great number of crescents were to be seen. These in the freshly-made slide of blood with very few exceptions retained their crescentric shape for only a few minutes (this activity in the change of form varies greatly in specimens of blood from different patients). They soon drew themselves up, thus straightening out the curve of the crescent while shortening themselves into the well-known ovoid form. After the lapse of from ten to twenty minutes most of them were quite round and extracorpuscular, the "bib" lying beside them as a delicate circle or "shadow of the red corpuscle." After from twenty to twenty-five minutes certain of the spherical forms became flagelleted; others, and especially those in which the pigment formed a definite ring and was not diffused throughout the organisms, remained quiet and did not become flagellated. The flagella broke from the flagellated forms and struggled about among the corpuscles, finally approaching the quiet spherical forms. One of them entered, agitating the pigment greatly, sometimes spinning the ring about; the rest were unable to enter, but swarmed about, beating their heads against the wall of the organism. This occured after from thirty-five to forty-five minutes. After the entrance of the flagellum the organism again became quiet and rather swollen; but although in the two instances in which this process was traced the fertilised form was watched for a long time no form analogous to the vermiculus was seen.

Note by Professor WILLIAM OSLER.—These observations of Dr. MacCallum are of very great interest and importance, and illustrate another step in our still scanty knowledge of the life-history of the malarial parasite. During the past two years Dr. MacCallum and Dr. Eugene Opie have been studying the hæmatozoa of birds, particularly with a view of ascertaining points in the life-history which might be suggestive in the study of the hæmatozoa of malaria. Their paper will appear in an early number of the *Journal of Experimental Medicine*.

Baltimore, U.S.A.

CONTRIBUTION TO THE SURGICAL ANATOMY OF THE TYMPANIC ANTRUM.

BY R. LAKE, F.R.C.S. ENG.,

SURGEON LARYNGOLOGIST TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION.

THOSE who have frequent occasion to open the tympanic antrum must constantly be forcibly reminded of its irregular position, especially as affects its relationship to the lateral sinus; those with the tympanum itself and also the facial nerve being fairly constant and only affected by the size of the antrum, whether that size be the result of disease or not. The results of careful measurements of twenty-eight temporal bones not affected with disease has enabled me to form a series of sketches, each typical of a certain number of sections. This number, whilst sufficiently large to give a fair approximate idea of the relationship of the sinus and antrum, is far too small to enable one to assume with any degree of certainty that it is correct.

The sections are cut horizontally, passing through the suprameatal fossa, which lies immediately above and behind the suprameatal spine, and is probably the best guide and landmark for the antrum which we possess. Each section has been carefully traced, these tracings compared by being superimposed. In this way the groups were formed, and a typical section was drawn for each group. In the figures an asterisk marks the position of the suprameatal fossa. These original groups are six in number, and may advantageously be further reduced into three main divisions—viz., (1) Those in which the groove for the sinus lateralis must be opened and the sinus exposed during the mastoid operation; (2) those cases in which the antrum is operated on—the probabilities are that the sinus will be exposed, yet it may escape; and (3) consists of those cases in which the sinus will not come into view during the operation. The bones used were all from adult skulls, children's and young adults' and diseased bones not being used. Group 1 is illustrated by Fig. 1, which shows the result of two sections; Group 2 is illustrated by Fig. 2, which shows the result of two sections; and Group 3 is illustrated by Fig. 3 (nine sections), Fig. 4 (six sections), Fig. 5 (seven sections), and Fig. 6 (two sections).

From these figures one would expect to expose the sinus about once in six operations, and by reference to my case-book I find that my own give a proportion or ratio of one in six. Besides these types certain exceptional varieties occur, notably those in which as a result of long standing chronic suppurative ostitis media the antrum is almost or entirely obliterated. In such cases the usual advice in text-books is not to pursue our researches to a greater depth than 15 mm.[1] This advice is certainly based on careful anatomical measurements, but apart from the difficulty of such measurements

[1] Politzer's Diseases of the Ear, English edition, 1884, p. 513.

Digitized by Google

there is a better guide now that most operators remove the posterior superior bony wall of the meatus, and that is to be careful not to proceed deeper than the level of the internal tympanic wall. Again, in cases of disease of the antrum where the cavity is of such a large size, as in Figs. 5 and 6, the curette must be used with considerable care on the anterior wall of the cavity, for having had a facial paralysis in such a case after operation which took some time to pass away, I examined the anterior wall of several such

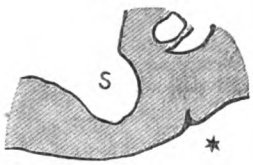

FIG. 3.

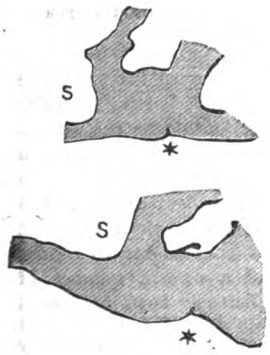

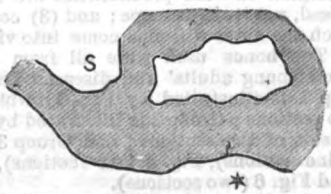

FIG. 4.

FIG. 5.

FIG. 6.

Figs. 1, 2, 3, 4, 5, and 6 represent the six primary groups of mastoid antra subdivided as above. S, Lateral sinus (at posterior end of section). * Suprameatal fossa. The antrum is not complete is Figs. 2, 3, and 5.

specimens and in more than one I found the facial canal imperfect for a certain distance or with an extremely delicate bony wall.

The act alone of exploring the sinus is one which, provided antiseptic precautions are taken, seems to be entirely without danger, and even where the sinus itself is opened careful plugging with iodoform gauze controls the bleeding and in no case has any ill effect been recorded, though the same cannot be said for puncture of the sinus with the drill. The use of the electric or dental burr is likely to reduce the number of times the sinus is exposed, as one can work with a straighter, that is a less funnel-shaped, wound in the bone, and it is usually due to to this alone that such accidents occur if the operator is working with a knowledge of the general position of the cavity. Continuing the relative measurements as far as one can from these sections, maintaining the original reservation that such a number can only give approximate accuracy, one finds the average depth of the attic to be a little over three-tenths of an inch, taken in a direct line from the point of election, and the distance of the nearest point of the sinus 0·48 in. on an average, with 0·2. in. as a minimum and 0·7 in. as a maximum; this last measurement demonstrates clearly that exposing the sinus by a continuation of a previous antrum operation is, as a rule, not only the proper surgical procedure, but the quickest route to the sinus, as the distance of the sinus is often less than a quarter of an inch from the suprameatal fossa.

Harley-street, W.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON THREE CASES OF FRACTURE OF THE CORONOID PROCESS OF THE ULNA.[1]

BY W. GIFFORD NASH, F.R.C.S. ENG.

OWING to the influence of Hamilton's writings the occurrence of this fracture is supposed to be extremely rare. Erichsen, in the ninth edition of his "Science and Art of Surgery," says that "it is one of the rarest accidents in surgery." Keating, in his "Cyclopædia of the Diseases of Children," says that he only knows of records of four cases in children—viz., those of Hamilton, Duer, Liston, and Annandale. In Hamilton's case, a boy, aged nine years, had a backward dislocation of the elbow, easily reduced, but recurring as easily. In Duer's case the fragment could be grasped between the thumb and the finger. Liston gives no details of his case. Annandale, whilst excising an old unreduced backward dislocation of the elbow, found the tip of the coronoid process broken off. Sir Astley Cooper, in his work on "Fractures and Dislocations," relates two cases. Case 1 was a man who fell and hurt his elbow; there was a dislocation of the ulna backwards, which recurred whenever the arm was extended. Case 2 was found in a dissecting-room subject and was complicated with fracture of the external condyle. Mitchell[2] records a case of backward dislocation of the ulna, in which he believed the coronoid process to be fractured, as the ulna easily slipped out of place when the elbow was flexed. I have reason to believe that fracture of the coronoid process is not such a very rare condition, as I have seen three cases which could not be diagnosed as anything else.

CASE 1.—A boy, aged twelve years, came to the casualty department at the Middlesex Hospital on Sept. 28th, 1888, having fallen on his outstretched hand and hurt his elbow, which, he said, moved in and out. On examining the elbow there was no dislocation present, but a swelling over the insertion of the brachialis anticus. On flexing the elbow crepitus could be felt, and whilst trying to determine the origin of this both bones suddenly became dislocated backwards. The dislocation was just as easily reduced and reproduced. There was no injury to the condyles or shaft of the humerus or to the olecranon process.

CASE 2.—A boy, aged eleven years, fell off a wall on to his left arm and hurt his elbow. Next day, Oct. 18th, 1890, he was admitted to the South Devon Hospital, Plymouth, where I was house surgeon. When seen the left elbow was much swollen and deformed, there being dislocation of the ulna and radius backwards and outwards. The head of the radius rotated with supination and pronation. The olecranon

[1] Read at a meeting of the Bedford Medical Society on Oct. 28th, 1897.
[2] Brit. Med. Jour., vol. ii., 1894.

Digitized by Google

process was uninjured. Both the condyles were sound and continuous with the shaft of the humerus. Crepitus was felt on moving the elbow and during reduction of the dislocation. Whilst flexing and extending the joint the dislocation was easily reproduced just as in the previous case.

CASE 3.—On Sept. 22nd, 1897, a boy, aged ten years, fell from the parallel bars in a gymnasium and, it is supposed, fell on his forearm. When examined there was found a wound over the inner side of the right elbow, through which the internal condyle projected. Both bones of the forearm were dislocated backwards and outwards. Chloroform was given and the dislocation reduced. It was easily reproduced. A finger in the wound explored the joint and found the coronoid process torn off the ulna and attached merely to the brachialis anticus.

These three cases were all produced by falls on the hand or forearm. In each there was dislocation backwards of the ulna and radius, the dislocation on being reduced being easily reproduced. Crepitus was present in the first two cases combined with swelling over the insertion of the brachialis anticus. The other bony prominences of the elbow were uninjured. In the third case, which otherwise exactly resembled the first two, the finger in the joint was able to determine the nature of the injury. These cases I am confident were all examples of this so called rare injury, which I feel sure will more often be diagnosed now that we have the Roentgen rays to help us.

Bedford.

A NOTE ON THE USE OF ANTI-STREPTOCOCCIC SERUM IN PUERPERAL FEVER.

BY C. J. STANSBY, M.D. BRUX.

CASE 1.—On Aug. 20th I was called to see a woman, the mother of nine children, who had been delivered by a midwife eight days previously. Her temperature was 102° F. and her pulse was 110. Milk and discharges were very scanty. There were no lesions of the passage or perineum. The case was clearly one of infection, as the midwife had had other cases in her practice quite recently. I ordered four grains of quinine, $\frac{1}{100}$ gr. of sulphate of atropia, and $\frac{1}{8}$ gr. of sulphate of morphia every four hours, with a vaginal douche. On the 21st the temperature was 103° and the patient became delirious and tried to get out of the window. On the 22nd the temperature was 105° and the pulse was 140. She was quite unconscious with muttering delirium. At 7 P.M. Dr. K. Lawson saw the patient with me and suggested a trial of the anti-streptococcic serum (Burroughs, Wellcome, and Co., dry); 18 c.c. were injected in the gluteal region, and the pills continued. On the 23rd I found that the patient had slept most of the night. The temperature at 9 A.M. was 101° and the pulse was 92; she was quite conscious. At 9 P.M. the temperature was 105·4° and the pulse was 120. A second injection of 10 c.c. was administered. On the 24th at 9 A.M. and 9 P.M. the temperature was 103° and the pulse was 100. A third injection of 10 c.c. was given. On the 25th the temperature at 9 A.M. was 100·5° and at 9 P.M. it was 103·5°; on the 26th at 9 A.M. and 9 P.M. it was 102°; on the 27th it was 100·5°; on the 28th it was 100·5°; and on the 29th it was normal. Convalescence was retarded by the formation of an abscess in the gluteal region. The chief point is that after the first injection the patient slept well, awoke conscious, and although the temperature subsequently rose to 105·4° she never lost consciousness, but always said she felt better.

CASE 2.—On Sept. 16th I was called to see a Kaffir girl, aged nineteen years, who had been delivered nine days previously of her first child. Her temperature was 104° F. She was noisy and delirious. Milk and discharge were entirely suppressed; a vaginal douche and pills, as in the first case, were ordered; and I gave an injection of 20 c.c. of the anti-streptococcic serum. On visiting the patient three days later I found her quite conscious. The temperature was 100° and she has, I hear, quite recovered.

In the first case, in absence of directions, the injection was made deeply into the gluteal region and resulted in an abscess; in the second case the injection was made under the skin between the shoulders without any subsequent trouble. These cases having been so satisfactory I shall on the first opportunity make further trial of the remedy.

Beaconsfield, South Africa.

PNEUMOTHORAX CAUSED BY DIRECT VIOLENCE WITHOUT FRACTURE OF THE RIBS.

BY WALTER KIDD, M.D. LOND.

THE following case seems to be worth recording on account of the rarity of the causation.

On June 2nd, 1897, a man, aged twenty-one years, fell backwards from the footboard of an omnibus to the road with his spine flexed. He must have fallen directly on the left side of his back, striking this part only, no other bruises or injuries being found elsewhere. He felt a sharp pain in the left hypochondriac region and left lower ribs, but was able to proceed a considerable distance to a volunteer drill, in which he took part, but after a few minutes he felt too ill to continue and returned home. That night he suffered great pain in the region mentioned and his breathing was embarrassed.

I saw the patient first sixteen hours after the accident and found him seriously collapsed. His skin was cold and clammy, his pulse was rapid and "running," and the respirations were hurried and painful, the pain being referred chiefly to the region of the spleen. After a full dose of opium he became easier and could be examined. There was no external sign of injury, no fracture of the ribs, and no hæmoptysis. The left side of the chest was hyper-resonant in front up to the clavicle and behind to the spine of the scapula; the heart-sounds were feebly audible in the epigastrium and cardiac impulse was faint; the respiratory murmur was absent except in deep inspiration, when it was markedly amphoric, and occasional metallic tinkling could be heard; tactile and vocal fremitus were barely perceptible. Under opium and stimulants the urgent symptoms passed off, no more pain occurred, and in three days from the date of the accident there was dulness at the base of the left lung posteriorly and marked splashing sound in succussion. It was evident that pneumothorax, with fluid in the pleural cavity, was present.

The patient's recovery was slow, and on July 5th, about a month from the date of the accident, there was still very deficient expansion of the lung and some pleural fluid was present with pyrexia, the temperature ranging from 101° to 102° F., and the apex-beat was with difficulty made out to have come within an inch of the normal position. On Aug. 17th the lung was fully expanded and little or no dyspnœa remained, though the heart was still displaced inwards. On Sept. 15th all symptoms had passed away, the lung was normal as to percussion and auscultation, and the apex-beat was at the usual spot.

This case appears to have been one of injury to the thorax without fracture of the ribs, causing rupture of some vesicle or vesicles of the lung in a healthy subject, and, if so, is one of a class rarer than those in which rupture of vesicles takes place in straining. It may be suggested that a small vomica near the surface had ruptured, but of the existence of such there was no evidence before the accident and none also after recovery had taken place.

Blackheath.

THE NURSES' HOME AT THE SWANSEA HOSPITAL.—The foundation-stone of the Nurses' Home, which is to be erected adjoining the Swansea Hospital in commemoration of the Queen's Jubilee, was laid on Nov. 3rd by the mayor (Councillor Watkins). Mr. E. Davies, the chairman of the hospital board, said that it was estimated that the home would cost £2250, of which at present only £800 had been subscribed, but the building would be completed by means of funds available from the Guesdon bequest.

FALMOUTH WATER-SUPPLY.—The question of the water-supply came before the town council at Falmouth on Nov. 4th. Dr. W. K. Bullmore, the medical officer of health, reported that the closest supervision would have to be exercised to prevent polluted water from finding its way into the reservoir. The manager of the waterworks, replying to the council's demand for efficient filtration, said that it was proposed to promote a Bill enabling the corporation to purchase the waterworks, and under these circumstances the company did not see their way to move in the matter.

UNIVERSITY COLLEGE HOSPITAL.

TWO CASES OF INTERSTITIAL HERNIA.

(Under the care of Mr. A. E. BARKER.)

IN 1835 Dance gave a short account of interstitial inguinal hernia, and in the following year a much fuller description of this condition was given by Goyrand.[1] In the form which is by far the most common it is associated, as in the second case recorded below, with an undescended testis. This may be explained by saying that the testis retained in the canal obstructs the downward extension of the processus vaginalis, and allows it to extend upwards and outwards between the two oblique muscles. The connexion of this form of hernia with the retention of the testis was conclusively shown by Tillaux[2] and by Dupuy.[3] Interstitial hernia is decidedly rarer in women than in men. For the notes of these cases we are indebted to Mr. Douglas Drew, surgical registrar.

CASE 1.—A woman, aged fifty-seven years, was admitted into University College Hospital on Feb. 5th, 1897, complaining of swellings in both groins. The patient was a widow, having been married twice. She had never had any children. Her occupation had been ordinary household work, but soon after her first marriage she did a good deal of hard lifting of heavy articles; since that time her work had been light. She had suffered at times from chronic bronchitis, from sciatica, and from influenza. Her family history was unimportant. She had been ruptured on the right side twenty years previously, but did not remember any definite cause for it. The rupture was easily kept up with a truss and gave her no pain until about two years before admission. About three years after the appearance of the rupture on the right side a rupture occurred on the left. This swelling was much harder than the one on the right and gave her much more pain. A double truss sufficed to keep the ruptures up until about a year before admission, when both came down frequently, even when the truss was on, and this was accompanied by a great deal of pain, sometimes necessitating prolonged rest in bed. A month before coming to the hospital both ruptures came down to an unusual extent and had to be reduced by her medical man. Ever since this she had been confined to bed. She had had no sickness but some nausea; her bowels had been made to act regularly by the aid of aperients. On admission a hernia was found in each inguinal region. The right was the larger, and the swelling extended into the right labium; the external ring was enlarged, and the structures superficial to it seemed to be somewhat atrophied by pressure. This hernia on the right side was readily reducible. Besides extending along the inguinal canal into the labium there was an extension upwards and outwards from the internal ring as far as the iliac spine, and this was especially noticeable when pressure was made over the lower part of the inguinal canal so as to prevent the hernia passing downwards. This upward extension of the hernia was seen to be interstitial, and after reduction the border of the internal oblique muscle could easily be felt. The hernia gave a good impulse on coughing, and the contents seemed to be nothing but bowel. On the left side was a smaller inguinal hernia, which also extended into the labium; it was reducible, but after reduction some thickening could be felt at the external ring which was noticeably enlarged.

On Feb. 11th Mr. Barker operated. The patient having been anæsthetised with gas and ether an incision was made over the right inguinal canal, and extended outwards to within an inch or so of the anterior superior iliac spine. The aponeurosis of the external oblique muscle and the external ring were exposed and laid open. The lower portion of the sac was easily shelled out, and the interstitial portion was very evident when the patient coughed. The two portions of the sac were divided by a well-marked groove, caused by the deep epigastric artery and vein crossing the centre. The lower part of the sac was pushed under the artery so that the whole sac was on the outer side of that vessel. The round ligament was divided and the sac, having been separated as far as its neck, was ligatured. The dissection was rather prolonged. The operation proceeded by Bassini's method; six deep sutures were necessary to close the internal oblique muscle and eight to close the external oblique muscle; a continuous suture was applied to the skin. On the next day the patient complained of severe abdominal pain and it was necessary to draw off the urine. No flatus had passed. The temperature was 100° F. The pain gradually diminished and the temperature fell until Feb. 20th, when the stitches were removed, the wound having healed completely. The catheter was needed for a few days longer. On March 4th Mr. Barker performed a radical cure by Bassini's method on the inguinal hernia on the left side. The wound healed by first intention, the temperature barely touching 100° on the 5th. The patient was discharged well on March 27th, 1897.

CASE 2.—A boy, aged twelve years, was admitted into University College Hospital on Oct. 27th, 1896, for a swelling in the right groin. He had always been in good health, though badly nourished. His mother had only noticed the swelling in the groin lately, but the patient said it had been there as long as he could remember. On admission an oval swelling about four inches in length in the right inguinal region was found; its long axis was obliquely placed and lay parallel to, but above, Poupart's ligament. By pressure the swelling was readily reduced through the internal abdominal ring, and after reduction the finger when placed over the internal ring slipped in as though the latter were almost patent, and a small oval mass was felt, probably the testis which was absent from the right side of the scrotum. On coughing the hernia protruded and extended upwards and outwards beneath the aponeurosis of the external oblique; it contained bowel, being resonant on percussion. The hernia did not extend at all downwards towards the scrotum.

On Oct. 29th Mr. Barker operated, the patient being under the influence of chloroform. An incision two and a half inches long was made over the inguinal canal and prolonged upwards and outwards in the direction of the fibres of the external oblique muscle. This muscle was exposed and slit up and the hernial sac was laid bare; its limits were defined and some long muscular filaments, evidently from the cremaster, were dissected off it; the mouth of the sac was large and came out through the internal ring; the sac itself was large and thin-walled and it spread out on every side from the mouth, so that it extended a certain distance towards the external ring and approached still more nearly the anterior superior iliac spine lying between the external and internal oblique muscles. The undescended testis was removed and the neck of the sac was tied in two places, the sac was cut off and the stump returned within the internal ring, which was then closed with five stitches. The incision in the external oblique muscle was sutured and the superficial wound was closed by a continuous stitch. The patient rapidly recovered from the operation, only a slight rise of temperature occurring and the wound healing by first intention. On Nov. 15th he left the hospital.

Remarks by Mr. BARKER.—These are the only cases of interstitial hernia it has fallen to my lot to operate on among some hundreds of operations for hernia. The only difficulty encountered was in the thinness of the sac in each case, which required care. In Case 1 the two portions of the sac separated by the epigastric vessels were long and sausage-shaped, with a common neck. In both cases the result has been excellent, Bassini's operation having in both been the one employed.

KENT AND CANTERBURY HOSPITAL.

A CASE OF CATHETER FEVER; DEATH IN TWENTY HOURS; NECROPSY.

(Under the care of Dr. T. WHITEHEAD REID.)

URETHRAL fever is ascribed to two entirely different causes. By some surgeons it is considered to be due to a reflex irritation of a kidney affected with acute or chronic interstitial nephritis, while others attribute it to the absorption of micro-organisms from the urethra. It is probable

Digitized by Google

that each of these suggested causes may suffice to give rise to urethral fever, but it has been customary to look upon those cases where death follows in a few hours after some slight urethral procedure, such as the passing of a catheter, as due to reflex action, as it is thought that the fatal result is too rapid for it to be due to sepsis; but Albarran has reported a case of internal urethrotomy in which the bacillus coli communis was found in the blood of the patient, who died twelve hours after the operation. On the whole, it may be said that the majority of the cases are due to septic infection, but that a few may be caused by reflex irritation.

A man, aged forty-seven years, was admitted to the Kent and Canterbury Hospital on Sept. 24th, 1897, for stricture. He first began to have trouble in passing urine ten years ago while in the army in India, where he served for fourteen years, and was several times treated for venereal disease and fever. Two years ago his stricture was dilated up to No. 8, but he neglected to continue the use of the catheter, and the difficulty in passing urine soon recurred. During the previous three months several attempts had been made to pass the catheter without success and without any untoward after-symptoms, until subsequently to an attempt on Sept. 1st he had a somewhat severe rigor, and on the next day commenced with a slight attack of facial erysipelas, which passed off satisfactorily. On admission the patient appeared to be in good general health. His urine was of specific gravity 1018, acid, and contained neither pus nor albumin. On the 25th, at 1 P.M., an attempt to introduce a catheter was made, several varieties of small-sized gum elastic and silver instruments being used, but without any of them reaching the bladder. The attempts were continued in all for about ten minutes, and were followed by no hæmorrhage from the urethra. At 3 P.M. he commenced to shiver and vomited after taking some brandy. At 3.45 P.M. the temperature was 104° F. He again vomited at 4.15 P.M., and passed fæces and urine involuntarily. He now became very restless and the pulse began to fail. At 5 P.M. the temperature had reached 106·6°. He was unconscious, and the pulse was imperceptible at the wrist. A hypodermic injection of strychnine and ether was given and an enema containing two ounces of brandy in six ounces of hot water, and he was cold-packed. He soon recovered consciousness as the temperature fell. The pulse also improved. At 6 P.M. the temperature was again rising and had reached 105 4°. Tepid sponging and cradling were ordered, with a repetition of the hypodermic injection. The temperature now gradually fell and at 11 30 P.M. was 100°. The pulse, however, was still only just perceptible at the wrist; otherwise he seemed to have got over the attack, and it was hoped that no further unpleasant development would arise. During the small hours of the morning, however, the heart again failed and the temperature steadily rose to 103·4°, and in spite of stimulants he died at 7 A.M. The urine after the rigor commenced was all passed involuntarily into the bed, but a specimen obtained from the bladder after death was loaded with albumin and showed 0·5 per cent. of urea.

Necropsy.—At the post-mortem examination (permission for which could unfortunately not be obtained until thirty hours after death) a long stricture in the spongy and membranous portions of the urethra was observed, with dilatation and hypertrophy of the urethra and bladder behind. There was no laceration of the mucous membrane of the urethra or dilatation of the ureters. The kidneys weighed eight ounces and presented no naked-eye changes save slight congestion. Decomposition was too advanced for microscopic examination to be undertaken. The heart weighed twelve ounces; the muscle was pale and flabby and the endocardium was deeply stained. None of the other viscera presented anything abnormal with the exception that there were a few petechiæ under the visceral layer of the pleuræ and some congestion of the bases of the lungs.

BULAWAYO HOSPITAL.

A CASE OF ABSCESS OF THE LIVER; OPERATION; RECOVERY.

(Under the care of Dr. FRANK ARNOLD, Resident Surgeon.)

WE cordially welcome the following communication from so outlying a portion of the British Empire as Bulawayo, and we gladly publish the case, as it is an excellent example of the good results which follow careful operative procedures in abscess of the liver. In THE LANCET of Oct. 2nd, 1897 (p. 858), we printed notes of two cases of hepatic abscess, treated by trans-thoracic hepatotomy, which resemble in many respects Dr. Arnold's case.

A man, aged thirty-four years, suffering from dysentery, was admitted to the Bulawayo Hospital under the care of Dr. F. Arnold on May 23rd. At the time of admission there was nothing peculiar about the attack beyond some slight pain in the right hypochondrium; this pain disappeared after a few days. On June 13th the patient was sufficiently well to be allowed up, and he continued to get up until the 19th. On that date, however, the temperature rose from normal to 101·4° F.; the bowels were loose, but not typical of dysentery; the pulse was frequent, soft, and regular; there was no rigor, the tongue was clean, and he was free from pain of any kind. These symptoms continued up to the 29th, the temperature rising at night to about 101° and falling to normal in the morning. The chest was repeatedly examined, for the patient began to waste rapidly and night sweats were noticed. On the evening of the 29th there was found one tender spot to pressure over a small area about the size of a florin in the ninth intercostal space; the skin here was not reddened, there were no dilated cutaneous veins, no œdema of the skin, and no flattening or bulging of this space; the liver was not enlarged. For the first time the patient complained of pain in the right shoulder, and there was some cough without any appreciable expectoration. Dr. Arnold suspected there might be a small collection of pus in the liver, and on the following day he inserted an aspirating needle in the ninth intercostal space slightly anterior to the line of the posterior axillary fold, and at a depth of one and a quarter inches reached a small collection of pus. All he could succeed in evacuating were about two drachms of curdled matter, looking very much like a mixture of strawberry cream and chocolate. The patient now improved somewhat; the evening rise in temperature became less, the bowels were moved once only instead of from two to four times in the twenty-four hours, the pain and cough were relieved, and Dr. Arnold would have felt disposed to think that he had emptied the abscess cavity had not the pulse still continued too frequent. On July 8th the temperature rose in the evening to 101 8° and continued to rise each evening subsequently to about 100° or 101°. On the 11th the diarrhœa again became prominent, and on the 12th Dr. Arnold aspirated in the same spot as before and drew off seven drachms of precisely similar pus, which, it may be added, was on both occasions quite free from smell. There was still no enlargement of the liver to be detected, but the superficial veins over the right side of the chest were more clearly seen than on the left, otherwise the appearance of the skin was normal. On the 17th it was decided to drain the abscess cavity, and Dr. Ernest Head, of Bulawayo, kindly gave chloroform. In operating in this case Dr. Arnold was guided by a description of a case under the care of Mr. Godlee.[1] Dr. Arnold resected about one and a quarter inches of the tenth right rib immediately anterior to the line of the posterior fold of the axilla, and as soon as he had removed this piece of rib there was a distinct firm bulging into the open space so formed. He divided the succeeding structures carefully until he considered that he had reached a depth which justified him in supposing that he was touching the diaphragm; the pleural cavity was not opened. It was then his intention to suture the diaphragm to the margin of the skin incision before proceeding any further, but the patient's condition did not allow of a prolonged operation, so he satisfied himself by the use of an exploring syringe that he was immediately over the abscess and opened it freely, evacuating about half a pint of pus with characteristics as before. On putting his finger into the abscess cavity he found that it was situated in the posterior part of the right lobe of the liver immediately under the diaphragm, and as far as he could judge was single. A large drainage tube was inserted and the case was treated in the ordinary way, the cavity being douched twice a day with warm boric acid and permanganate of potassium solutions, and wood-wool pads applied as dressing. With the exception of one or two evening rises of temperature, which readily yielded to quinine, and were probably malarial, the temperature afterwards ran a normal course; but the bowels kept loose and the pulse frequent, although the wound was perfectly healthy and the discharge free from smell. It was concluded that the patient was not yet free from dysentery and he was limited to a strictly milk diet and the large bowel was washed out daily with a solution of quinine

Digitized by Google

(1 in 2000), about a couple of pints being used at each irrigation. Five or six days of this treatment removed the last symptom of dysentery and reduced the pulse-rate to normal. Two months after the operation the patient left the hospital in excellent health with merely a scar along the course of his tenth right rib to remind him of his abscess.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Cystic Tumour of the Bladder containing Calculi.—Cases of Mesenteric Cyst in Young Children.

A MEETING of this society was held on Nov. 9th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Mr. P. J. FREYER read a paper on an Obscure Cystic Tumour of the Bladder containing Two Calculi; successful Removal by Suprapubic Cystotomy. The patient, an Anglo-Indian, aged thirty-six years, had suffered for ten years from obscure urinary symptoms, which he dated from a fall in the cricket-field in 1886, by which he hurt his loins. The injury was followed by pain in the region of the right kidney, intermittent hæmaturia, pyrexia, and cystitis. The most prominent symptom for several years latterly was that the patient could never empty his bladder in the natural way. With much straining he could pass two or three ounces of urine, when the stream stopped, and he could only empty his bladder by passing a catheter or by lying down. High fever accompanied by much pus in the urine periodically occurred. When free from fever his urine was of a pale straw colour and of low specific gravity. The patient was extremely thin, weak, and depressed from long suffering. He was repeatedly sounded by various surgeons, but no stone was felt. Under these circumstances he was sent home in the autumn of last year. Mr. Freyer saw the patient first on Sept. 24th, 1896, and carefully sounded him, but found no stone. He suspected the presence of a tumour of the bladder which obstructed the flow of urine by falling against the neck of that viscus. He arrived at this conclusion through having seven years ago successfully removed, by a perineal opening, a pendulous fibroid tumour of the bladder from a patient who had suffered from this particular symptom. The cystoscope confirmed the suspicions, at once revealing a smooth tumour the size of a walnut, with thick rounded pedicle growing from the right side of the base of the bladder. On Sept. 30th the bladder was opened suprapubically, and a tumour was felt by the finger the size of a walnut, smooth on the surface except at the apex, where a small papilloma was growing from it, slightly bi-lobed, and attached by a round tense pedicle to the bladder wall near the right ureteral opening. On twisting off a portion by forceps and then drawing the tumour into the abdominal wound it proved to be cystic, and contained two uric acid calculi, one the size and shape of a nutmeg, the other the size of a large pea, the two weighing forty-two grains. The tumour had been rendered tense by the calculi and contained urine, but was now lying flaccid, like the finger of a glove, inside the bladder. The tumour was again drawn out into the wound, the pedicle was clamped, the tumour was excised, and the pedicle cauterised. A needle armed with silk was then passed through the pedicle behind the clamp and tied in two parts, taking the ends of the ligature out through the abdominal wound, and dressed as usual. Perfect recovery ensued, the ligatures on the pedicle coming away on the tenth and twelfth days respectively, and the wound completely closing within a month. The patient had had no urinary symptoms since, has put on flesh, and twelve months after the operation was in perfect health. Special attention was directed to the following points. 1. The nature and origin of the tumour and how the calculi got inside it. Microscopically it was found to be a single-walled cyst composed of fibrous tissue, and covered both inside and outside by transitional epithelium such as is found in the bladder and ureters. It was probably formed by the calculi passing down from the kidney as far as that portion of the ureter which passes obliquely through the bladder wall, stopping short of the ureteral opening; that, impelled onwards by the force of the urine, they bulged the bladder and ureteral walls inwards, and that in this way eventually a pendulous cystic tumour containing the calculi, and communicating by a narrow opening with the ureter, was formed. In the operation the cyst and contents were excised, the ureteral wall repaired, and the ureteral opening left untouched and patent. 2. The advantage of the cystoscope for diagnosis in obscure urinary disease. 3. This was, as far as Mr. Freyer was aware, the first instance in which a ligature has been applied to the pedicle of a bladder growth. The result suggests the more extended use of the ligature in tumours of the bladder and prostate for checking hæmorrhage, &c.; but care must be taken to bring the ends of the ligature out through the wound so that eventually they may come away, and not cut them short for fear of a phosphatic concretion forming on their ends.—Mr. A. E. BARKER agreed that the pathology of this case was that given by Mr. Freyer—namely, that the cyst was due to the bulging out of an obstructed ureter. He was familiar with cases in which calculi block the orifice of the ureter and cause a swelling and protrusion of the mucous membrane, giving rise to the appearance of a tumour with a central dimple corresponding to the ureteral orifice. But this was the only case he knew of in which the orifice could not be seen. He remarked on the absence of renal symptoms and asked whether there were any signs of irritation or distension of the kidney such as occur after the ureter has been occluded by a ligature.—Mr. MORGAN thought it unusual that the symptoms should have existed for so long without leading to more disturbance of health. Assuming the explanation of the retention by the blocking of the urethral orifice by the pendulous cyst to be correct, it was difficult to see what happened to the urine from the affected ureter at the periods when clear urine was being passed from the bladder. He was inclined to think that the ligatures were superfluous after clamping and cauterisation. He quoted one case in which a stone became impacted in the posterior wall of the ureter just as it enters the bladder. The stone was buried in exuberant granulations and was not discovered at the first exploration of the bladder, but at a second operation an incision was made into the mass and a stone was found in a cyst just below the orifice of the ureter.—Mr. HURRY FENWICK mentioned a case which had been published by Sir Thomas Smith in which a similar protrusion cyst from the ureter was found post mortem. In that case, however, the cyst did not contain calculi. He did not feel quite certain that the explanation which had been given of the tumour in the present case was the only possible one. It could be seen by the cystoscope that in almost all cases in which there was a calculus in the ureter a prolapse of the ureteral mucous lining took place of a similar character to the prolapse of the rectum in children. This prolapse often attained a considerable size and had a tendency to turn upwards. Was it not possible that Mr. Freyer had removed a cystiform protrusion of this kind? He thought that the ligature of the pedicle involved the grave risks of septic absorption, of hæmorrhage when the ligatures separated, and of leaving a sore which was apt to heal slowly and to become crusted over with phosphates. He preferred to clamp, cut off cleanly, and cauterise.—Mr. FREYER, in reply, said that while the patient was under his care there were no signs of hydronephrosis. Possibly the affected kidney had become totally destroyed at an earlier date. He also would prefer as a rule not to use ligatures, but at the time of the operation he did not know with what cavity the cyst communicated, and so he thought it wiser to ligature it securely off.

Mr. F. S. EVE read a paper on Mesenteric Cysts, with two cases in young children. The first case was that of a male infant, aged eleven weeks, who was admitted with a very freely moveable fluctuating tumour on the right side of the abdomen, which was diagnosed as a mesenteric cyst. He had gradually wasted since birth, and had constantly suffered with diarrhœa and vomiting. On May 1st laparotomy was performed. A cyst the size of a Tangerine orange was found in the free margin of the mesentery, the small intestine coursing over it. Two ounces of turbid serum were removed by aspiration. The cyst was attached to the abdominal wall and was opened a few days later and a drainage-tube inserted. Convalescence was rapid and uneventful, a fistula being left. The child appeared to have recovered, but on June 6th, nearly six weeks after the operation, was suddenly attacked with convulsions and collapse and died in a few hours. No cause for this was discovered at

Digitized by Google

the necropsy. There was a slight organic narrowing of the intestine where attached to the cyst, probably due to arrest of development. The second case was that of a male child aged three and a half years, who was admitted with acute intestinal obstruction of four days' duration; the abdomen was distended, and the patient was much exhausted by incessant vomiting. Dulness was noticed in the right lumbar region, but the tumour was obscured by distended coils of intestine. Laparotomy was performed; and a large cyst containing thirty-two ounces of serous fluid occupied the right flank; it was situated in the free margin of the mesentery and compressed the intestine. The cyst was excised and the mesentery sutured. Death occurred from shock and as a result of the previous obstruction nine hours after operation. At the necropsy there was no peritonitis. The cyst was found to be situated seven feet above the ileo-cæcal valve. These two cases illustrate the typical symptoms of mesenteric cyst in the earlier and later stages. The first had symptoms resembling gastro-enteritis with emaciation, the second typical intestinal obstruction without definite premonitory symptoms. In the first case all the physical signs of mesenteric cyst were well marked with the exception of the presence of a band of resonance over the tumour. In the second case the tumour was entirely obscured by coils of distended intestine; dulness on percussion was the only indication of its presence. Reference was made to the various abdominal tumours which may be mistaken for mesenteric cyst and a classification of mesenteric cysts was given, and it was pointed out that these two cases belonged to a group of lymphatic or serous cysts which were supposed to originate in the lymphatic glands of the mesentery. The cyst wall in the first case contained much unstriped muscle tissue. This was also observed in a specimen in the Museum of the Royal College of Surgeons of England. The fluid was albuminous and contained cholesterine. References were also made to more recently reported cases of mesenteric cyst possessing unusual characters. As regards treatment Mr. Eve held that drainage after attaching the cyst wall to the parietes was preferable to excision on account of its greater safety. The former was by no means an ideal operation, and its dangers and drawbacks were pointed out. The literature of the subject showed the rarity of mesenteric cysts in children.—Dr. H. D. ROLLESTON said that in the first case the microscopic appearances suggested that the cysts might have arisen from intestinal diverticula such as were occasionally present in the upper part of the large intestine. He had seen a case in which there were many small diverticular cysts at the upper part of the small intestine, and in a case recorded by a French observer there were 300 of these cysts. He thought this a better explanation than that the cysts were lymphatic retention cysts. Referring to some remarks which had been made about the position of Meckel's diverticulum Dr. Rolleston remarked that that structure did not occur in a constant position. In one case in which it had been present in an adult it was situated seventy-two inches from the cæcum.—Dr. NORMAN MOORE said that there was in the Museum of St. Bartholomew's Hospital a specimen with many small diverticular cysts along the mesenteric attachment of the jejunum. He thought that it was unlikely that a Meckel's diverticulum proper would ever become sealed off at its intestinal end.—Mr. MORGAN asked where the incision was made in operating on these cases.—Dr. R. A. GIBBONS asked for particulars of the mode of transfusion.—Mr. EVE, in reply, said that he admitted that the pathology of the cyst was not satisfactorily explained. The wall of the intestine just opposite to the cyst was quite smooth and showed no sign of any diverticulum. The incision in both cases was made in the middle line near the umbilicus. Intravenous transfusion with normal saline solution was employed.

The PRESIDENT announced that at the next meeting of the society on Nov. 23rd there will be a discussion on the Prevention of Enteric Fever, which will be opened by Dr. Vivian Poore.

MEDICAL SOCIETY OF LONDON.

Mitral Stenosis.—Cretinism.—Inoperable Tumours treated with Injections of Coley's Fluid.—Obesity.—Multiple Subcutaneous Tumours.—Employment of Rectangular Splint after Excision of the Mamma.

A CLINICAL meeting of this society was held on Nov. 8th, the President, Dr. A. E. SANSOM, being in the chair.

The PRESIDENT showed two cases of Mitral Stenosis of definite Rheumatic Origin. The first was that of a girl, ten years of age, who had had recent attacks of rheumatism. She showed marked increase of cardiac dulness both to the right and to the left of the normal area. A heaving impulse was felt with the ventricular systole over the right ventricle and not over the left. A thrill was felt to the right of the apex, but it did not terminate abruptly. There was a systolic murmur at the apex, not obscuring the first sound, which was loud and had the character of a snap or tap. A short presystolic murmur was heard internal to the apex. Dr. Sansom thought that the case illustrated an early period in the pathogenesis of mitral stenosis. He regarded it as probable that rheumatic endocarditis was still in evidence and that there was some mitral regurgitation from this cause; but he considered that the physical signs showed mitral stenosis to be the preponderating lesion. The second case was that of a young woman, aged twenty years, of poor physique, who had had rheumatic fever three times, the first in childhood and the last nine weeks ago. At the present time there was some increase of the cardiac dulness to the right and the apex beat was diffuse. A slapping first apical sound was followed by a prolonged murmur, unmodified by respiration, having its maximum to the right of the apex, fading off to the left, but was still audible at the angle of the left scapula. The aortic second sound could be heard at the apex. She had had several attacks of hæmorrhage from the stomach, not due to gastric ulceration, and there were other signs that the venous circulation was impeded, and that there was as well "starvation of the aorta." It was to this that he attributed the nervous symptoms that the patient frequently presented, as well as the stunted growth and the dyspepsia.—Dr. SEYMOUR TAYLOR expressed his opinion that practically all the cases of mitral stenosis in early life were of rheumatic origin or due to chorea, which he believed to be one of its manifestations. He thought that in the second case in addition to the physical signs which had already been mentioned as indicating the existence he could make out with his finger dilatation of the left auricle. He thought that the "snap" which was described was the relic of a murmur which could probably be reproduced by making the patient exert herself. He thought that dry-cupping was of the greatest service in such conditions, and sometimes wet-cupping or venesection was beneficial.—Dr. DE HAVILLAND HALL remarked that these cases often did not respond to digitalis at first. He usually began treatment by applying half-a-dozen leeches to the hepatic region and administering calomel internally. He agreed with Dr. Taylor as to the nature of the snap in the first case, and that the vast majority of cases of mitral stenosis in the young were of rheumatic causation.—Dr. SANSOM, in reply, said that he quite agreed with previous speakers as to the rheumatic causation of mitral stenosis. French observers were disposed to exclude rheumatism in regard to mitral stenosis and to try to drag in a tuberculous process to bolster up this doctrine; and the case would be found well stated from that point of view in Potain's "Cliniques de la Charité."

Dr. W. S. COLMAN showed a child, nine and a half years of age, who was an example of Partial Cretinism. She was now just 3 ft. high and only weighed 2 st. 2 lb. When she first came under observation, in June, 1897, she showed the following signs of cretinism: stunted growth, absence of any accessible thyroid gland, fat masses in the anterior triangles of the neck, thick lips, and puffy eyelids. There were lordosis and prominence of the abdomen. Although she had not previously been treated with thyroid extract there was an entire absence of the usual train of nervous symptoms associated with cretinism. She was alert and intelligent, being in the second standard at school, and her facial expression was bright. She had been taking three grains of the dry thyroid extract since June, and her appearance now was much less characteristic than at that time. In the four months she had grown two and a half inches. Dr. Colman thought that the escape of the nervous system was probably best to be explained on the assumption that there was an accessory thyroid whose secretion was adequate for the nutrition of the brain, but insufficient for the general nutrition of the body.—Dr. FLETCHER BEACH said that the degree of mental development in this case was very remarkable. He had never seen a case with so little mental defect or such educational capacity even after thyroid treatment, and in this case it appeared that there was no mental impairment even before the case came under treatment.—The PRESIDENT said that

Digitized by Google

there must be many of these partial cases going about unrecognised, and it would be well to watch for them and treat them with thyroid glands.

Dr. WALTER CARR showed a case of Sporadic Cretinism treated with thyroid extract. The child was five years old when she first came under observation in February, 1896, and she then presented a typically cretinoid appearance; her height was 30 in. and her weight was 24¼ lb.; her hair was coarse and scanty; the skin was dry; there was no sweating; the hands were broad, the temperature was slightly sub-normal, and the abdomen was very protuberant; she could walk very little, could say only a few words, and took no notice; no thyroid gland could be felt. Development had been very slow, and when two years old she had only four teeth. She was given at first one 5 gr. thyroid tabloid a day, but as this caused a rise of temperature to 102° F. it was reduced to half a tabloid. Gradual improvement set in; she sweated profusely, the pulse got faster, and the temperature became normal; her weight fell at first to 20 lb., and then slowly increased, the cretinoid aspect disappeared, and the intelligence steadily improved. The dose of thyroid extract has been slowly diminished, and for the last four months she has only taken one 1½ gr. tabloid every third day. She now appears to be a healthy, intelligent child and goes to school; her height is 37½ in. and her weight 37 lb.

Mr. MANSELL MOULLIN showed two cases in which Inoperable Tumours had almost disappeared after the repeated injection of Coley's fluid. The first was a man, twenty-eight years of age, who was admitted in November, 1895, for a swelling in the groin, which he had noticed for four weeks. There was a firm, fixed, non-fluctuating swelling lying underneath the right iliac vessels, and there were several enlarged glands over it. The skin was not red or fixed and did not pit on pressure. He looked ill and there was some irregular pyrexia up to 101° F. Treatment was commenced on Oct. 4th with half a minim of Coley's fluid. There was slight reaction. The next day the injection of a larger dose was tried and there was no reaction, and injections of increasing strength were given every three or four days, reaching eight minims in February, when the treatment was discontinued. On one or two occasions he had rigors after the injections. His general condition improved and he gained 7 lb. in weight. The tumour at first increased rapidly, but in January it appeared to be acutely inflamed, and from that date it rapidly shrank, and by March only a trace of it could be felt, and since then it has scarcely altered. The second case was that of a man, forty-eight years of age, who was admitted in November, 1896, for an abdominal tumour. On examination the left flank was found to be occupied with a large swelling of irregular shape, hard, not fluctuating, and not connected with the skin or the abdominal muscles. It descended into the iliac fossa and reached upwards under the false ribs. There was no glandular enlargement and very little pain. When treatment was commenced on Dec. 16th, 1896, the tumour was rapidly growing. The injections, which were gradually increased as in the last case, were not as a rule followed by reaction; but on Dec. 29th and again on Jan. 29th, 1897, there were rigors. At the time of the latter rigor the tumour became acutely inflamed, the skin being red and œdematous, so that there was some fear of suppuration. As this subsided the tumour continued to shrink more and more until at the present time very little of it could be felt. Mr. Mansell Moullin said that there was no actual proof that these tumours were sarcomata, but that was the opinion formed by all those who had an opportunity of examining them carefully. They were certainly not gummata and there was nothing to suggest an inflammatory origin; if they had been they would almost certainly have suppurated under the treatment. He considered that the treatment was not free from danger. He had seen one case in which a feeble patient died after the second injection. Coley had published twenty cases in which the treatment had been applied successfully. He himself had tried it in nine cases altogether, and in three the growths practically disappeared, and in two the size underwent considerable diminution.—Mr. WATSON CHEYNE said that he had seen two cases in which the treatment had been employed, and in neither was there any definite good result. It was curious that the treatment appeared to benefit only cases of spindle-celled sarcomata.—Dr. COLMAN said that he had had the opportunity of examining two tumours post mortem, in one case ten days and in the other ten months after the injection of Coley's fluid. In the first there was a cavity at the site of the injections containing two drachms of yellow fluid composed of broken-down cells, and in the older case there was an ordinary cicatrix at the sites of injection. The injection had not arrested the growth of the tumour.—The PRESIDENT asked how the fluid was diluted for the administration of the smaller doses.—Mr. MANSELL MOULLIN, in reply, said that he used sterilised distilled water as a diluent. He had never had the opportunity of inspecting a tumour after injection, but in one case now under treatment a part of the tumour had sloughed out.

Dr. DE HAVILLAND HALL exhibited a man, aged forty-two years, as an example of obesity relieved by thyroid medication. The patient was admitted into the Westminster Hospital on Aug. 17th, 1896, suffering from Partial Hemiplegia with a previous history of sciatica and gout. He stated that he weighed 28 st. On Aug. 29th he was found to weigh 24 st. 11 lb. 8 oz. He was put on nitrogenous diet and given iodide of potassium. On Sept. 8th a thyroid tabloid was ordered daily. On Sept. 11th he had two daily and on Oct. 3rd three a day. His weight steadily went down to 21 st. 10 lb. 3 oz on Oct. 30th. Since his discharge from the hospital he had continued the same diet as far as possible, and had had one thyroid tabloid daily for most of the time. His weight at the present time is 19 st. 5 lb. While under treatment there was marked diuresis up to 90 oz. per diem, and the urea varied from 2·2 per cent. to 3·8 per cent.

Dr. GEORGE TEMPLETON showed a case of Multiple Subcutaneous Tumours, probably Fibro-lipomata, occurring in a healthy single woman, twenty-nine years of age. Seven years ago she noticed a small, hard, moveable swelling under the skin of the right loin, her attention being directed thither by slight pain. Since then several others had made their appearance, commencing as small, round, hard nodules, and gradually increasing, the largest now being one and a half inches across. Some twenty-four of them were scattered over the trunk and limbs, but not on the face. They were free from pain except when irritated by the clothing; the pain was then of a dull, aching character. When manipulated the smaller ones were fairly hard and moveable; the larger ones were rather more fixed and appeared to contain more soft fibrous tissue and fat than did the others. She did not know of a similar condition ever having existed in any of her relatives. Up to the present she had not consented to have any of them removed for microscopic purposes.—Dr. DE HAVILLAND HALL referred to a similar case which he had seen in a man of advanced years who ultimately developed fibroid phthisis. They gave rise to no serious symptoms and persisted for many years. He employed many remedies, including arsenic in large doses, without any result. He thought that the tumours in Mr. Templeton's case were fibro-lipomata.—Mr. F. C. WALLIS thought that sarcoma was excluded by the duration and by the condition of the patient, and he agreed that they were fibro-lipomata.—Dr. SYMONS ECCLES asked whether the hard or the soft tumours were the older.—Dr. TEMPLETON, in reply, said that the tumours were hard at first, and then appeared to undergo a fatty metamorphosis.

Mr. COTTERELL showed a patient treated with an Axillary Rectangular Splint after Excision of the Mamma, with free removal of the pectoral muscle. The arm was placed at a right angle to the trunk, instead of being bound to the side. The idea was suggested to him by Dr. Heaton, and the result in this case appeared to be most successful. He agreed that it was too early, fifteen days after the operation, to be certain that there would be no cicatricial contraction, but the patient could already use her arm to do her hair, and he thought that if she used the arm regularly there would be little risk of contraction. There had been no pain after the operation, although there was usually discomfort or cramp when the arm was bound tightly to the side.

OBSTETRICAL SOCIETY OF LONDON.

Abdominal Hysterectomy for Myoma of the Uterus.—Exhibition of Specimens.

A MEETING of this society was held on Nov. 3rd, the President, Dr. C. J. CULLINGWORTH, being in the chair.

Mr. BLAND SUTTON read a paper on Abdominal Hysterectomy for Myoma of the Uterus, with Brief Notes of Twenty-eight Cases. He said that recent improvements in the methods

Digitized by Google

of performing hysterectomy had been followed by such good consequences that abdominal hysterectomy for myomata of the uterus too large to admit of vaginal myomectomy was now rapidly gaining favour, and it was becoming a plain duty to point out to patients with uterine myomata, as was done when they had ovarian tumours, that the earlier the tumours were removed the less the operative dangers and therefore a diminished peril to life. It was for the purpose of showing how safely uncomplicated myomata of the uterus could be dealt with that he ventured to place before the society brief records of twenty-eight cases operated upon at the Chelsea Hospital for Women and the Middlesex Hospital. Whenever possible, especially when operative interference was necessary during the menstrual period of life, he reversed the conditions of oöphorectomy, so that instead of removing the ovaries and Fallopian tubes and leaving the uterus and tumour he removed the uterus and tumour and left one or both ovaries with the corresponding Fallopian tube. This happened in fourteen cases in the subjoined list. The immediate results of this method were admirable, and spared the patient at least the inconvenience of an acute menopause.

Under 30	1

	28

Only one patient had ceased to menstruate previously to the operation.

Mr. ALBAN DORAN insisted that whilst an ovarian cyst nearly always caused death if not removed, a large number of uterine fibroids remained stationary and harmless. Others, however, entailed discomfort and danger, and then the surgeon must consider which was the safest operation. Altogether the retro-peritoneal method seemed the best. He found that in cases where the tumour was large but the cervix free the operation was especially satisfactory. The arteries were easily reached or felt and secured, the cervix could then be divided, and the healthy mucus which it contained was free from germs. The patient was saved from the inevitable direct and secondary evils of the serre-nœud. This advantage was marked in six very anæmic cases where he had successfully operated; in one there was a sloughing sub-mucous growth which caused no trouble after the operation. He had lost two cases where the operation had certainly been deferred far too long; unhealthy mucus in the cervix was a source of peril in sickly subjects. No operation for burrowing and cervical fibroids could be free from danger; enlarged branches of the uterine arteries were here a source of peril. Mr. Doran objected to leaving the Fallopian tubes behind, and always endeavoured to take them away with the uterus undivided. Their contents were often unhealthy. As to the abdominal sutures no method was perfect. The numerous reports sent in at the Geneva Congress in 1896 tended to show that in every case the last method adopted by each authority was the best insurance against hernia. The fallacies in such evidence were obvious.

Dr. PLAYFAIR said that he agreed as to the great practical interest of Mr. Sutton's paper, but first he must take exception to the sweeping conclusion that had been arrived at that removal of the appendages was not to be performed in any case of fibromyoma. In his experience in properly selected cases it was one of the most valuable operations, and the results were occasionally most brilliant. He was aware that this was not the opinion of the most forward school of hysterectomists either in America or England, who seemed to hold that the mere existence of a fibromyoma, whether it produced symptoms or not, was a sufficient ground for hysterectomy. He held this theory to be most dangerous and untenable. Dr. Duncan had shown that evening quite a small fibroid not bigger than a large orange which he had removed by hysterectomy. Some of the Fellows had criticised this procedure and said he should have removed it by vaginal enucleation. He contended, however, that if Dr. Duncan had performed oöphorectomy he would have subjected the patient to infinitely less risk and have obtained quite as good a result. The small mortality, which was practically *nil*, following oöphorectomy was one of the chief grounds for selecting it in suitable cases. Even in Mr. Sutton's cases there had been a mortality of 7 or 8 per cent.; conceive what it would be in less experienced and skilful hands. It seemed to him absurd to compare the risks to which the patient was subjected in performing oöphorectomy and hysterectomy. Another point he might remark on was the operation to be selected. He felt sure that the extra-peritoneal method and clamp were doomed. The long painful convalescence was most terrible, and no fact seemed to him more certain than that the intra-peritoneal plan had come to stay. He strongly advocated suture of the parietes by three separate layers.

Dr. HORROCKS was surprised that no mention was made of Baer, who first described the operation. Dr. Galabin published a paper on it, and later Mr. Harrison Cripps brought forward some cases before the society. At the discussion on that paper he (Dr. Horrocks) had ventured to describe the operation with the serre-nœud as a barbarous one; and although exception was taken to the word at the time opinion was now largely against this so-called old operation. In one case, after using the serre-nœud, the patient had so much pain from the dragging of the pedicle that he opened the abdomen the second time and completed the operation by Baer's method, and the patient had been well ever since. One thing surprised him very much and that was the large number of cases operated upon by certain operators. He could not but think that in many of these cases no operation whatever was required, for it was a well-known fact that fibroid tumours were in the majority of cases innocent tumours. They stood on quite a different footing from ovarian cysts, which almost invariably proved fatal when left alone. This point had a bearing on the mortality of Mr. Sutton's cases, for if all the twenty-eight cases were severe cases of fibroids, causing grave symptoms of hæmorrhage and such like, the loss of two, or a mortality of 7 or 6 per cent., could not be called great. He had performed the operation twelve times with one death in a case complicated with albuminuria. Each of these cases was most serious, and none of them so small as some of those in Mr. Sutton's list. He could not agree that the mortality of the operation was as low as that of ovariotomy. He thought 7 per cent. a high mortality in ovariotomy in these days of asepsis. He entirely agreed on one point—viz., the importance of leaving the patient one or both ovaries when they were healthy. He himself had done this in several instances and considered it a far greater mutilation to remove the ovaries than to remove the uterus.

Dr. C. H. ROBERTS thought it was a pity that the history of the cases had not been fully given, particularly as regarded the symptoms which had rendered the operations described necessary. He could not agree with Mr. Sutton in many points; surely a very large number of fibroids seen did not require operation at all. He thought the sweeping assertions as to clamp and belt made by Mr. Sutton were undeserved.

Mr. MEREDITH expressed his entire dissent from the views held by Mr. Sutton regarding the duty of recommending early operation in cases of uterine fibromyoma, a course rightly adopted in the case of ovarian tumours. The two diseases are not comparable as regards the necessity for operative interference since the great majority of fibromyomatous growths do not tend to imperil life and may never require surgical treatment, while ovarian tumours, on the other hand, inevitably prove fatal unless removed. It should be borne in mind that the fact of recovery after an operation by no means absolutely implies that the treatment adopted was a necessary procedure. Mr. Sutton's views on the value of the intra-peritoneal treatment of the uterine stump would appear to be founded upon somewhat insufficient data—viz., the results of only twenty-six operations, of which two proved fatal. The speaker's experience with the serre-nœud had given him eighty-three recoveries out of a succession of ninety abdominal hysterectomies, including a run of thirty cases without a fatality and two series of forty and forty-seven respectively with but two deaths in each, results which had not as yet, so far as he knew, been equalled by advocates of the intra peritoneal method. At the same time, however, he fully recognised the advantages of the shorter convalescence required by this latter plan of treatment, and he had therefore now adopted it for some six months past with very satisfactory results. Mr. Sutton did not hesitate to say that the operation of oöphorectomy had now been entirely superseded by intra-peritoneal hysterectomy; but he (Mr. Meredith) still considered the operation in question to be a most valuable and efficient method of treatment in suitable instances, giving a mortality in his experience of something under 3 per cent. A considerable proportion of cases of abdominal hysterectomy, especially where the lower segment of the uterus is tolerably

Digitized by Google

free from growth, will recover easily whether the stump is secured by the serre-nœud or by ligature; but, on the other hand, many tumours are to be met with which will tax to the utmost the knowledge and skill of the operator, and the wise surgeon will reserve to himself the power of selecting in any given instance the method of treatment which from his own experience he deems most likely to secure the best result for his patient.

Dr. WILLIAM DUNCAN quite agreed with Mr. Sutton that the intra-peritoneal method of performing hysterectomy was far superior to the extra-peritoneal method in which a clamp had to be used and the stump left to slough away. He published in THE LANCET about six months ago a list of eighteen consecutive cases which comprised every case (hospital and private) he had performed in which only one death occurred, and that took place on the eighteenth day from pulmonary embolism when the patient was considered convalescent. He quite agreed with Mr. Doran that the appendages should be removed as well as the tumour, for in not a few cases of fibroids of the uterus it is well known that the tubes contain pus, hence a source of danger if these are left. Seeing the remarkable success that attended this operation he was strongly of opinion that oöphorectomy for fibroids should be allowed to lapse into oblivion even in cases of small tumours, for oöphorectomy in these cases has a mortality of at least 5 per cent.

Mr. BUTLER-SMYTHE thought credit was due to Mr. Sutton for so clearly pointing out the additional risks attending the performance of the so-called pan-hysterectomy. These risks were not imaginary, but there was a real danger to the ureters, one or both of which might easily be cut across or included in the lowest ligature. His (Mr. Butler-Smythe's) ideas on the subject under discussion were so absolutely opposed to the views held by Mr. Sutton that he would like to ask him what the signs and symptoms were which would lead him to perform hysterectomy. In his opinion not one fibroid in twenty required removal, and he was now speaking of large tumours and not of those similar to the one exhibited that evening.

Dr. GRIFFITH entirely agreed with those who held that the intra-peritoneal method was the preferable operation. No one who had followed the progress of many cases operated upon by the two methods would hesitate to admit the greater freedom from suffering during convalescence and the general well-doing exhibited by patients after the intra-peritoneal operation. His conviction was that the operation of enucleation of fibroids in suitable cases with proper antiseptic methods was a very safe and preferable operation, leaving the patient with a perfect uterus as well as ovaries.

Dr. HEYWOOD SMITH said that in 1892 he read a paper elsewhere on Sub-peritoneal Hysterectomy, which he contended described the operation better than intra-peritoneal. In it he brought forward cases by Goffe (New York) and Milton (Cairo), as well as some by himself, and he was glad to find the most advanced operators were pursuing that method to the exclusion of the serre-nœud oöphorectomy and so-called pan-hysterectomy.

The PRESIDENT said he had had an opportunity of declaring his views on the subject before them so recently—namely, in the discussion which took place last year upon Mr. Harrison Cripps's paper—that he would not occupy more than a few minutes with his remarks on the present occasion. He agreed with Mr. Sutton in regarding the operation he had described as superior to that of so-called pan-hysterectomy. He also agreed as to the desirability of leaving if possible one or both ovaries. The trend of modern surgery was in the direction of removing nothing that could be avoided and in sparing wherever possible, both in male and female, one or both of the essential organs of reproduction in operating for diseases in which those organs were involved.

Mr. BLAND SUTTON, in reply, expressed amazement at the singular course the discussion had taken. He never for a moment anticipated that the horrid clamp would find a single supporter. The clamp in the treatment of hysterectomy was doomed, and he ventured to predict that in five years' time no operator would be found unwise enough to advocate its use. In regard to the wound he said a yielding cicatrix after any form of abdominal operation in which the wound was secured by a single row of sutures was in a certain proportion of cases inevitable.

The following specimens were exhibited:—

The PRESIDENT: (1) Fibroma of the Ovary; (2) Gangrene of an Interstitial Fibromyoma of the Uterus; (3) Fibromyomata of the Uterus causing Intestinal Obstruction and Death after the Menopause; and (4) Early Ectopic Gestation complicated by Fibromyomata of the Uterus.

Mr. TARGETT (for Dr. WILLIAMSON): Sarcoma of the Uterus causing Inversion; and (2) Intra-pubic Joint producing Diminution of the Pelvic Inlet.

Dr. PLAYFAIR: Carcinoma of the Cervix Uteri; removed by Total Extirpation, the ovaries and tubes having been removed two years previously.

Dr. WILLIAM DUNCAN: (1) Large Myoma of the Uterus and Tumour of the Left Ovary; and (2) Small Interstitial Fibroid of the Uterus removed by Abdominal Hysterectomy.

Dr. JOHN PHILLIPS related the subsequent history of "A Case of Ruptured Uterus."

HARVEIAN SOCIETY OF LONDON.

The Treatment of Lateral Curvature of the Spine.

A MEETING of this society was held on Nov. 4th, Dr. MILSON, President, being in the chair.

Mr. NOBLE SMITH read a paper on the Treatment of Lateral Curvature of the Spine and gave a demonstration. He pointed out the advantages that were to be derived from mechanical assistance in addition to other methods of treatment. It was stated by the advocates of exercise treatment alone that deformity in the bones could not be remedied, and it was remarked that a test of this deformity was the existence of "rotation." Mr. Noble Smith had found that it was quite possible by means of the hands alone to hold a patient in a straight position although slight rotation had commenced, and it was possible to maintain that position by means of apparatus until the bones had readjusted themselves. He demonstrated the action of the apparatus upon several patients whom he exhibited, showing that the chest was left perfectly free from pressure, that there was no interference with development or with the use of the muscles, and that the pressure was so gentle that it acted rather by encouraging the patients to hold themselves erect than by force alone. Mr. Noble Smith stated that children quickly realised the comfort and benefit of wearing the apparatus. If there was pain or aching or a sense of weakness these symptoms were quickly removed. In older patients in cases of severe deformity the necessity of such treatment was, he thought, obvious, as it was almost the only way of relieving pain, a result which could always be attained. A few useful exercises were then demonstrated, and especially one which tended to counteract "rotation." Treatment by exercises alone only acted temporarily, the spine falling back towards the old position, whereas by means of apparatus the results were kept up in the intervals. The difficulty of forming a correct diagnosis between caries and lateral curvature in the early stages was referred to, and it was urged that great caution should be observed with regard to exercises during this uncertain stage. Mr. Noble Smith then proceeded to demonstrate the application of the treatment by forced reduction of the deformity. He stated that the application of this plan of treatment, which had recently attracted so much attention in France (especially in reference to cases of caries), was well shown in the case of the patient exhibited. This was of course a case of lateral curvature, for which deformity he considered the forced reduction quite safe, whereas in caries it was a dangerous remedy. A photograph had been taken of the back before treatment was commenced and another after an interval of three weeks. Three operations had been performed during these three weeks, at each of which something was felt to give way like the breaking down of adhesions, and after each operation great improvement was found to have taken place. The patient's back showed a marked improvement upon the photograph taken before treatment.

Mr. JACKSON CLARKE said that there was much misunderstanding as to the various methods of treating lateral curvature. In the lateral curvature of rickety infants instrumental treatment was absolutely necessary. A moulded leather back splint which left the chest and limbs free was the best form of support in such cases. Some surgeons were under the impression that they used exercises alone in the treatment of lateral curvature. Mr. Roth's plan consisted in placing the patient for three-quarters of an hour every day on a firm table and then putting the patient through a series of exercises. In this method the table was an instrument which the weight of the patient brought into play. And, further,

Digitized by Google

this plan required the patient in the intervals between the exercises to recline on a special couch, which was also an instrument having the same action as the upright part of a Chance's splint as modified by Mr. Noble Smith. The lateral arms of a Chance's splint had the same action as the "lateral sling" recommended by Mr. Barwell. Thus there was less difference between the methods of various surgeons than at first sight appeared. He (Mr. Clarke) had under his care a great number of patients wearing Chance's splint with the best results. Instruments such as felt corsets or mechanical contrivances that surrounded and cramped the chest were to be avoided. Young men with strong muscles and good muscular instincts could be sometimes successfully treated without wearing an instrument.

Dr. HARE expressed himself as convinced of the value of the treatment by apparatus as carried out by Mr. Noble Smith, whose methods he had watched with great interest in patients whom he (Dr. Hare) had sent to him.

Dr. BOWLES remarked that having at one time been opposed to treatment by apparatus he had become converted to this plan of dealing with lateral curvature from having seen the benefits derived by patients under the care of Mr. Noble Smith. In elderly patients, especially those suffering from complications of the chest, he had seen excellent results.

Mr. DODSWORTH spoke in favour of this treatment. He had submitted members of his own family to Mr. Noble Smith's care with the most gratifying results, and he had also many of his patients under his treatment with equally good effects.

Mr. ROB CARTER (Anerley) had seen the results of Mr. Noble Smith's treatment in quite twenty cases, and he could say that in every one the benefits had been very decided. Some of these patients had previously undergone treatment by exercises, but with unfavourable results, and several of them who were severely deformed were eventually perfectly cured by means of the apparatus. One great point in favour of this treatment was, he thought, that the patients were able from the first to continue their ordinary avocations and were not laid up for a single day.

Dr. SCANES SPICER related a case which had been treated by Mr. Noble Smith, in which there was very considerable deformity. The patient was so perfectly cured after four months' treatment that an eminent physician who was subsequently consulted stated that he could then find nothing whatever the matter with the spine.

Mr. GAY asked to what extent the pelvis was affected in cases of scoliosis, and the PRESIDENT inquired as to the length of time required for treatment.

Mr. NOBLE SMITH, in reply, stated that the time required varied according to the case.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Cerebral Hæmorrhage in a Child.—Gunshot Injuries in the late Greco-Turkish War.

A MEETING of this society was held on Nov. 5th, Dr. H. P. POTTER, President, being in the chair.

Mr. MAITLAND THOMPSON read the history of a case of Cerebral Hæmorrhage in a Child. A boy, aged thirteen years, was at school, and had just passed through an attack of chicken-pox, and while quiet during convalescence he one day in the morning complained of headache and vomited. An hour later he was unconscious. There was no strabismus. Both legs were extended, but there was no voluntary movement in them. Convulsions soon afterwards set in and the temperature rose, and the patient died ten and a half hours after becoming unconscious. At the necropsy the vessels of the meninges were found to be much congested and the brain substance of the right temporo-sphenoidal lobe was ploughed up by blood. Mr. Thompson alluded to the rarity of such cases and to the difficulty of diagnosis.—Dr. S. BONTOR mentioned a similar case, that of a female child who on rising in the morning felt giddy. When seen shortly afterwards she was dull and had vomited. There was no evidence of paralysis or of cerebral irritation. The patient died the same evening. Post mortem there was found a large hæmorrhage on the right side of the brain which had opened into the ventricle.—Mr. BRINDLEY JAMES also alluded to a like case in a boy.—Dr. W. COLMAN said cerebral hæmorrhage in early life was very rare, and the records of the Children's Hospital in Great Ormond-street had scarcely any cases in them. He had, however, seen one case associated with ulcerative endocarditis.—Dr. J. D. MORTIMER said he knew of one specimen in the Great Ormond-street Museum. He mentioned various causes of cerebral hæmorrhage which might occur in children—viz., asphyxia, purpura, miliary aneurysms, and chronic nephritis.—The PRESIDENT mentioned some details of three cases which had been brought before the Pathological Society, in two of which the hæmorrhage appeared to have been venous in origin, while the third was a case of infantile scurvy.

Dr. H. J. DAVIS next read a paper on Gunshot Injuries in the late Greco-Turkish War, and illustrated it by a description of cases and by specimens of projectiles. Having alluded to the various forms of bullets used on both sides in the recent war he proceeded to describe the characteristics of the wounds formed by each. There was but little damage done in many cases by the rifle bullets of the Mauser type owing to their great velocity. Shell wounds were likely to be the most lacerated. He averred that there was great difficulty in diagnosing the presence of a fracture in many cases, probably owing to the fact that such was only partial in most instances, the bullets passing clean through. Wounds of the upper extremity seemed to cause much less trouble than those of the lower limb. Wounds of the joints with care and antisepsis by no means always did badly. He mentioned "seton" wounds in which the bullet traversed an extent of tissue close beneath the surface, and advocated that these should be freely opened up and cleansed. Thoracic and abdominal injuries were severe in most cases, and only one soldier was operated on by laparotomy, he being alive when brought in. One case of acute emphysematous gangrene was prevented from infecting other wounds by careful isolation. He had to thank Mr. F. C. Abbott for allowing him to mention the details of some of the cases under his care.[1]—Dr. THUDICHUM gave recollections of three campaigns through which he had been. He thought modern bullet wounds showed much less contusion than former ones, but that artillery wounds were more serious than they used to be.—Dr. SYMONS ECCLES had been through the Russo-Turkish War, and alluded to the fact that the wounds of that campaign appeared to differ but little from those of the recent war. He would like to know the proportion which the dead bore to the wounded and what influence malaria had upon wounds.—Dr. DAVIS, in reply, said it was impossible to find out accurately the proportion of dead to wounded, but thought that the latter were more numerous. Nearly every man who was injured had a rise of temperature afterwards and many showed signs of malaria.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Presidential Address.

THE first general meeting of this society was held on Oct. 27th at 20, Hanover-square, London, W., the President, Dr. ANDREW S. MYRTLE (Harrogate), being in the chair.

The report of the treasurer was read and adopted, the success of the society's "Journal," which is now almost self-supporting, being especially noted.—Dr. MYRTLE moved that the President-elect, Dr. Wm. Vicary Snow, of Bournemouth), take the chair.—A vote of thanks to the retiring President was moved by Dr. THEODORE WILLIAMS and seconded by Sir RICHARD DOUGLAS-POWELL, Bart.—In his reply Dr. MYRTLE emphasised the fact that practitioners at health resorts were not antagonistic to the general practitioner, but were desirous of working with him, or rather under him and after him.—A vote of thanks to Dr. Hyde, the editor of the "Journal," was moved by Mr. BLAKER (Bognor), supported by Dr. LEWIS (Folkestone), and acknowledged by Dr. HYDE.—Dr. MYRTLE, jun., moved, and Dr. GAGE BROWN seconded, a vote of thanks to the treasurer, the council, the secretaries, and auditors, which was acknowledged by Mr. KEETLEY, Mr. WARD-HUMPHREYS (Cheltenham), Mr. MACFARLANE (Brighton), and Dr. SUNDERLAND.

The first ordinary meeting of the session was then held, the President, Dr. W. VICARY SNOW, being in the chair. Sixteen candidates were elected fellows of the society.

[1] Mr. Abbott's cases will shortly be published in THE LANCET.

Digitized by Google

Dr. SNOW delivered his Presidential Address, in which he described the climatic features of Bournemouth, with special reference to the effect of the pine woods on diseases of the lungs.

Dr. BAGSHAWE (St. Leonard's) moved, Dr. IVOR MURRAY (Scarborough) seconded, and Dr. MYRTLE supported a vote of thanks to the President for his address.

A motion was then submitted by Mr. ALFRED HAVILAND advocating the establishment of a chair of Medical Climatology and Geography. This having been seconded by Dr. THEODORE WILLIAMS and supported by Dr. CLIPPINGDALE was carried, and the Council was instructed to consider the matter and take such steps as seemed desirable.

HUNTERIAN SOCIETY.

Exhibition of Cases.

A CLINICAL meeting of this society was held at the London Institution on Oct. 27th, Dr. G. E. HERMAN, the President, being in the chair.

Sir HUGH BEVOR showed a case of Congenital Heart Disease in a youth aged twenty-one years, in which he considered the physical signs as indicative of a patent ductus arteriosus.

Dr. J. H. SEQUEIRA showed a case of Congenital Heart Disease in a child aged ten years who exhibited signs of arrested physical development. He also showed a case of Chronic Hydrocephalus in a girl aged eleven and a half years with marked arrest of mental and physical development.

Dr. F. J. SMITH brought forward a case of Proptosis in a woman who had been under observation for two years. There was also congestion of the conjunctiva on the outer side of both eyes, with œdema of the eyelids and enlargement of the veins.

Mr. A. H. TUBBY exhibited a case showing the Removal of the Left Half of the Tongue, Left Submaxillary Gland, and Left Anterior Pillar of the Fauces for epithelioma of four months' duration. The patient was a man aged fifty years and he had made an excellent recovery.

Mr. COTMAN exhibited the Radiograph of a case of Disease of the Left Ankle-joint; the patient also was present.

Remarks on the cases were made by the PRESIDENT, Dr. HINGSTON FOX, Mr. TUBBY, Dr. F. J. SMITH, Dr. GLOVER LYON, Mr. RAWES, and Mr. GROGONO.

LIVERPOOL MEDICAL INSTITUTION.

Dissecting Aortic Aneurysm. — Thyroidectomy. — Sporadic Cretinism.—The Immediate Correction of Deformity in Pott's Disease.

A MEETING of this society was held on Nov. 4th, Dr. RICHARD CATON, President, being in the chair.

Dr. GLYNN narrated a case of Dissecting Aortic Aneurysm. The patient, a man aged thirty-four years, died from dissecting aneurysm of the aorta. Dr. Glynn also exhibited the specimen, which showed that the whole of the thoracic and abdominal aorta was involved. The patient had suffered from infective endocarditis at the age of fourteen years, and had since been the subject of aortic regurgitation. During life the symptoms of mitral stenosis were present, but post mortem no mitral stenosis was found. The man died from dissecting aneurysm rupturing into the pericardium.—Dr. A. C. E. HARRIS and Dr. CARTER made comments on the case.

Mr. F. T. PAUL read notes of a case of Partial Thyroidectomy for Parenchymatous Goitre, which ended fatally two and a half days after operation from thyroidism. From this and other cases he concluded that the symptoms described were due to the absorption of an excessive amount of thyroid secretion through the wound. He advised that the gland should be handled gently during the operation and that the isthmus should be ligatured before being severed. If the symptoms still supervened the wound should be laid entirely open, irrigated, and filled with antiseptic gauze, which must be changed as often as it became moist.—Dr. ALEXANDER and Mr. RUSHTON PARKER made some remarks.

Dr. ABRAM read notes of a case of Sporadic Cretinism with a Note on the Nitrogen Excretion. The patient, a girl aged fourteen years, had suffered from cretinism for about two years. He administered thyroid extract for six weeks, in which time the patient increased one and a quarter inches in height. He considered that the administration of thyroid extract increased metabolism as shown by the larger excretion of nitrogen.—Dr. CARTER remarked that if waste from any cause occurred, such as excessive labour, &c., the output of nitrogen was immediately increased. This child, like all myxœdematous patients taking thyroid, lost weight; but he was unable to see that the determination of the total nitrogen proved that the action of the thyroid on metabolism was direct any more than the mere fact of the loss of weight proved it.—Dr. STANLEY GILL, Dr. GLYNN, and Dr. P. DAVIDSON made comments upon the case.

Mr. ROBERT JONES read a paper on the Immediate Correction of Deformity in Pott's Disease, illustrated by lantern slides. He had operated on a very large number of cases since July with results which had exceeded his expectations. Sufficient time had not elapsed to allow him to advocate so bold a procedure with any degree of dogmatism. However, with ordinary precautions no immediate ill-effects followed He had no case of abscess, no case of disseminated tubercle, and none of paraplegia. Where paraplegia had existed the extension and pressure had either improved or cured it. He pointed out the tendency to bony ankylosis in caries of the spine which was not found in tubercle of other joints. This inspired the hope that the separated vertebræ would become firmly united and that the danger of the so-called gap might prove illusory. The cases showed the disease in various regions and some of them exhibited great deformity. The duration of some extended over several years. After describing Calot's method of reduction Mr. Jones adversely criticised the plaster corset and advocated a splint so constructed as to keep the spine in lordosis. He found that the curves best suited to obliteration were those occurring in the young where the disease was active and where the angle of deformity was changing. The curves most easily reduced were those involving several rather than few vertebræ and those situated in the dorsal region.—Mr. R. W. MURRAY said that he had operated upon fourteen children, whose ages varied from two and a half to nine years. They were all selected cases, the children, apart from the spinal trouble, being in good health. The immediate results had been entirely satisfactory, but in one case where the disease was in the upper dorsal region weakness of the upper limbs and exaggerated knee-jerks appeared one month after operation. He drew attention to the high mortality of tuberculous disease of the spine amongst the poor and also to the remarkable absence of the formation of new bone. This being the case he feared that the gap formed between the bodies of the diseased vertebræ after the forcible correction would not be filled up by bone sufficiently strong to bear weight. Should this prove to be the case the patient would have to rely indefinitely upon instrumental report or have a return of the "hump-back." While this method of operating was still in the experimental stage he intended to rest content with what he had already done and to await further results. In the immediate future he would operate only on cases in which paralysis existed.—Mr. RUSHTON PARKER said that he had performed this operation both with and without an anæsthetic; in the latter case there did not appear to be much pain caused by the proceeding. He considered the Thomas's double hip splint a great improvement upon the plaster jacket. He looked forward with hopeful interest to the application of Calot's method. — Mr. THELWALL THOMAS drew attention to the fact that forcible interference with tuberculous bone disease did not produce paralysis, abscess, or dissemination of tubercle—three theoretical "bogies" which had been handed down from text-book to text-book. Recent experience in forcible dealings with joint disease gave surprisingly good results, and he felt sure that permanent success would follow a large number of cases treated by Calot's method.—Mr. GEORGE HAMILTON pointed out that in estimating the amount of improvement in paralysed cases after Calot's method had been used it was important to recognise that many such cases recovered from the paralysis under the classical methods of treatment. He could quote many such in his own practice.—Mr. A. DAVIES thought that the operation was not justifiable except in carefully selected cases.—Dr. GLYNN, Dr. STANLEY GILL, Mr. NEWBOLT, and Mr. SHELDON also took part in the discussion.—Mr. R. JONES replied.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Intradural Tumour of the Spinal Cord.

A MEETING of this society was held on Oct. 26th, Dr. SINCLAIR WHITE, the President, being in the chair.

Mr. PYE-SMITH called attention to a valuable method of Using the Electro-magnet for the Detection of Steel or Iron Foreign Bodies, whether small enough to be extracted by it or not. The method consists in attaching the magnet by means of a transformer to the wires for the supply of electric light by an alternating current. When thus used a vibratory sound is heard when the magnet comes in contact with the foreign body, continuing as long as the contact lasts.

Mr. DALE JAMES showed (1) a case of Pityriasis Rubra (Hebra) which had improved greatly under his treatment; and (2) an Anomalous Case of Ichthyosis.

Mr. HERBERT HALLAM showed (1) a Photograph of a case of Bilateral Herpes Zoster Faciei; and (2) a Large Perinephritic Sarcoma.

Dr. WILKINSON gave particulars of a successful case of Suprapubic Cystotomy with immediate Suture of the Bladder.

Mr. ARCHIBALD CUFF showed a patient on whom he had performed Intestinal Resection and End-to-end Anastomosis for Sarcoma two months ago. The man was subjected to two operations. The first included the cutting away of the growth which was found in a hernia and the formation of an artificial anus. The second, performed some months later, consisted of opening the abdomen, resecting the two ends of the bowel, and end-to-end apposition. The anastomosis was performed with the help of Mayo Robson's bone button.

Dr. BURGESS read notes of a case of Intradural Tumour of the Spinal Cord. The growth, a sarcoma, ovoid in shape, with diameters of 1 inch and ¾ inch, was situated in front of the cord about the level of the attachments of the roots of the fourth dorsal nerve to the cord. The chief symptoms were burning pains in the legs, which gradually extended up the abdomen, loss of power beginning in one leg, extending in the course of three or four weeks to the other and ultimately becoming complete in both, rectal and bladder trouble with signs of cystitis and pyelo-nephritis. The most striking feature of the case, however, was marked dissociation of sensations of heat, pain, and touch which began in and was most pronounced in the legs, but extended up to the fourth costal interspace. The sensation of touch was not much impaired, that of pain was greatly impaired, whilst thermic sensibility was absolutely lost in the legs.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases.—Pasteur Anti-rabic Treatment.

THE first ordinary meeting of this society was held on Nov. 3rd at the Medical Institute, Birmingham, Mr. J. W. TAYLOR, President, being in the chair.

Dr. HAZELWOOD CLAYTON showed five members of a family of Hæmophiliacs—viz., two boys, their mother, their uncle, and their maternal grandmother. The family history exemplified the law governing the inheritance of hæmophilia—viz., that the disease is transmitted through the female line to the male children although the females themselves escape. In other words, the sons of the daughters suffer. The great-great-grandmother had seventeen children, seven of whom were boys, and all bled to death; her daughter (the great-grandmother) had sixteen children eight of whom were boys, all bleeders, and seven bled to death; the grandmother (daughter of the above) had sixteen children, six of whom were boys, all bleeders, and only two are living; the mother (daughter of the above) had five children, three of whom were boys, all bleeders. The above history also shows the extreme fecundity of the female members of hæmophiliac families.

Dr. DOUGLAS STANLEY showed a specimen of Tumour of the Middle Lobe of the Cerebellum. The patient was a girl, aged twenty-three years, who had suffered from occipital headache and vomiting for ten weeks. There was no optic neuritis. There was some giddiness at times, but no paralysis of any kind, and the reflexes were unaltered. Breathing failed suddenly, and artificial respiration was kept up for twelve hours, after which the heart's action ceased.

Professor ALLEN read a paper entitled "Personal Experience of the Pasteur Anti-rabic Treatment." He recounted his impressions of the Pasteur Institute in Paris. He gave details of the treatment, including the method of preparing the immunising fluids. He described the constitutional effects of the inoculations and gave the latest statistics of the results of the treatment.

Reviews and Notices of Books.

Archiv für Pathologische Anatomie und Physiologie und für Klinische Medicin. Herausgegeben von RUDOLF VIRCHOW. Band CL., Heft 1. (*Virchow's Archives.* Vol. CL. Part 1.) Berlin: G. Reimer. October, 1897.

THE commencement of the 150th volume of his world-known *Archiv* must be a source of great pride and pleasure to the eminent founder of this famous journal; and very fittingly his portrait is placed as a frontispiece to the volume. Professor Virchow himself contributes the opening article, "Unser Jubelband," in which he states that the prospectus of the first number is dated April, 1847, and since 1852, when his original co-editor, Professor B. Reinhardt, died, he has himself been solely responsible for the conduct of the journal. How well he has acquitted himself of his task the series of volumes, which contain many of the most noteworthy contributions to medical science during these fifty years, eloquently testifies. He claims, and with justice, that the guiding principle of his work has been the introduction into pathological study of biological methods and the dethronement of all so-called "systems." To one whose retrospect goes back for half a century it may well seem that pathology has been revolutionised; and undoubtedly the leader of this changed method of the study of pathology is Rudolf Virchow himself, who we trust may long be spared to guide and control the work of building up the science of medicine on the firm and broad foundations which he had so great a share in laying. The number of the *Archiv* before us contains: (1) The text of Professor Virchow's address at the Moscow Congress on the Continuity of Life as the Basis of Modern Biological Doctrine; (2) An interesting paper on the Experimental Production of Amyloid Degeneration, by Dr. Carl Davidsohn, the agency used being injections of cultures of staphylococcus pyogenes aureus; (3) Fungi and Fungus-poisons in the Brain and Spinal Cord, by Dr. J. Seitz; (4) the Pathological Anatomy of the Malpighian Bodies of the Kidney, by Dr. A Böhm; (5) Tumours of the Submaxillary Gland, by Dr. G. Löwenbach; (6) the Mechanism of Closure of the Urinary Bladder, and Urination, by Dr. E. Rehfisch; (7) a further contribution to the study of Pneumothorax, by Dr. Sackur; (8) the Connexion of Section of the Vagus with Degeneration and Inflammatory Changes in the Heart-muscle, by Dr. A. Hofmann; and (9) the Quantitative Estimation of Glycogen in the Liver, by Dr. A. E. Austin, of Boston, U.S.A.

Sleep; its Physiology, Pathology, Hygiene, and Psychology. By MARIE DE MANACÉINE (St. Petersburg). London: Walter Scott, Limited. (The Contemporary Science Series.) 1897. Pp. 341. Price 3*s.* 6*d.*

THE problems of sleep have exercised many minds, but have perhaps received more attention from the public than from medical men. The book now under consideration is written in rather a popular style but yet in a truly scientific spirit, and will doubtless be read with interest by all who enjoy the study of an enticing subject. The authoress has evidently given much time and attention to the compilation of this volume and is certainly to be congratulated on the

Digitized by Google

success of her endeavours. That she is much in earnest is shown by her opening words: "It would be difficult to find any aspect of life towards which so much injustice and ingratitude have been shown as towards sleep, for not only do we profit continually by all the benefits of sleep, but even above them; yet we pay no attention to its phenomena and do not even include it among the questions deserving of serious study."

The Physiology of Sleep is fully dealt with, all the principal theories with regard to its causation being fully examined. The authoress, however, is not satisfied with any of those hitherto propounded and prefers to evolve one of her own. She states: "We have already seen that an arrest of consciousness may always be observed in the sleeper, and if we wish to understand the nature and causation of sleep on the psychic side we must study consciousness itself. From this point of view the cause of sleep may be stated in the formula: Sleep is the resting-time of consciousness." Many interesting facts are brought forward in favour of this theory, both from observations in animals and in human beings.

The chapter on the Pathology of Sleep is also well written, showing a considerable amount of original study. The subject is roughly divided into two sections; in the first sleep is "weakened," that is to say, there is insufficient sleep, and in the second we have the condition of "narcolepsy" or prolonged and abnormal sleep. Such sleep for the most part only occurs in isolated cases, but it is sometimes found in various countries as an endemic disease, being there known as the sleeping sickness, hypnosia (Dangain), and by various other names. Automatism and Somnambulism naturally receive their share of attention; likewise hysterical somnolence and double personality.

The Hygiene of Sleep is also well thought out. One theory contained therein strikes us as being rather novel—namely, that anæmia in young girls is due to albuminuria caused by prolonged sleep, so that in the treatment of that condition it is desirable to diminish the time devoted to sleep, and also to avoid too prolonged retention of the urine during the night. We should have preferred the view that drowsiness is a symptom rather than a cause of anæmia. The final division of the book deals with the Psychology of Sleep. The care which has been bestowed on the writing of the book is shown by the copious bibliography given at the end of each of the chapters.

LIBRARY TABLE.

Transactions of the Reading Pathological Society. Vol. I. Fifty-fourth Session, 1895-6. Edited by the President and Honorary Secretaries. 1896 Reading: Beecroft and Alexander. Pp. xxx. and 124.—When on Oct. 20th, 1896, the Pathological Society of London celebrated the Jubilee of its formation an address of congratulation was received from the only pathological society in England which was older than itself, and that was the Pathological Society of Reading. Founded on July 13th, 1841, it has maintained a vigorous existence for more than fifty years, and at last has determined to issue a volume of Transactions. Very much good work must have been done in those fifty years, if we may judge of it by a *résumé* which is prefixed to the present volume, though naturally some of the treatment advised in the papers read in the earlier years of the society is somewhat out of date; thus in one paper free bleeding was recommended before and after ligaturing the innominate artery for aneurysm so as "to prevent the disturbance of the circulation which follows on tying so large a vessel." The [illegible] are held at the Royal Berkshire Hospital, where the [illegible] a museum and a library. The meetings take place monthly, except in August, on the Wednesday nearest the full moon—we presume in order that the members may have the benefit of the moonlight in returning to their homes. Living specimens and "card specimens" are exhibited at each meeting and papers are read. In this volume of Transactions are many papers of great interest, and we will refer to some of those which appear to us to be of most importance. Dr. A. Ashby has an article on the Relation of the Public Health Service to Pulmonary Consumption, in which he discusses the question, "Should Consumption be made Notifiable?" Dr. Ashby as medical officer of health for the Reading Urban District had been asked to advise the sanitary authority on this point, and in his reply he stated that he did not advise the compulsory notification of the disease, but thought it would be of great value if rooms and bedding were disinfected after deaths from phthisis. In his paper he urges that there should be inspection of slaughtering, so that diseased carcasses might be recognised before the viscera have been removed. The value of tuberculin in the diagnosis of tuberculosis in dairy cows is acknowledged, and Dr. Ashby considers that in many ways the Public Health Service may do much to restrict the prevalence of tubercle in the human race. Mr. Hastings Gilford contributes a paper in which he strongly advocates the earlier getting up of patients after labour; in fact, he objects to the name "patients" as erroneous and points out that the quickened circulation which results from sitting and standing is in favour of the early involution of the uterus, and he quotes the opinion of Dr. Charles White, of Manchester, who wrote at the end of the last century in support of his contention. Dr. C. W. Marriott describes five cases of Nerve Lesion which he had under his care in the Royal Berks Hospital; the first case was one of paralysis of both musculo-spinal nerves apparently due to cold; paralysis of this nerve on both sides is rare, except when due to the use of crutches. Another case was one of facial paralysis apparently due to syphilis and disappearing rapidly under the administration of potassium iodide. Dr. J. B. Hurry describes a case of Addison's Keloid occurring in a young man, nineteen years of age. Two papers on Anæsthetics are in the volume. In one Mr. J. H. Walters describes two cases of death from chloroform and one in which recovery occurred; in one of the fatal cases and in the non-fatal case the failure of the pulse was markedly earlier than the failure of respiration. In the other paper Dr. G. Stewart Abram endeavours to discover the safest anæsthetic, and decides that ether is unquestionably safer than chloroform. Mr. Gilford gives notes of eight cases of Dwarfdom (we must acknowledge that we have never met with this word before); one of the cases he had observed himself, and the accounts of the others are culled from other writers. He suggests that certain dwarfs are the subjects of a definite disease, characterised by the partial atrophy of those structures which are hypertrophied in acromegaly; one valuable argument advanced is found in the case of a dwarf named "Princess Josepha," whose sister was 6 ft. 8 in. high, and was the subject of acromegaly. It is a little confusing in this paper to find some of the measurements given in centimetres and some in inches; it would be much better to give both forms. Dr. J. A. P. Price contributes an interesting case of Chronic Intestinal Obstruction due to Constriction of the Small Intestine by Meckel's Diverticulum, the obstruction due to this cause being nearly always of the acute variety. The volume concludes with a paper by Mr. Treves, on the Surgery of the Peritoneum, which was read before the society in October, 1896. We have dealt somewhat fully with the contents of this book as it is the first attempt at publication made by a society which has existed so many years and done so much good work. We hope to see the volumes of Transactions appearing regularly every year.

Official Reports of the Republic of Costa Rica.—Among the official reports recently presented to the members of Congress of the Republic of Costa Rica there are two relating to the National Institute of Hygiene in San José, the metropolis. The work of this establishment during the past year included a considerable number of chemical analyses as well as many histological and bacteriological examinations of urine, fæces, sputum, tumours, &c. Larvæ and ova of the ankylostoma duodenalis were discovered in five out of sixteen samples of fæces. The institute is amply provided with apparatus for the production of the Roentgen rays and for micro-photography. Dr. Emilio Echeverria, the director, mentions incidentally in his report that at the ordinary pressure at San José water boils at 95° C. (203° F.), a circumstance which of course shows that the town is situated at a great elevation. In connexion with the institute there is a department, presided over by Dr. Bojas, for the preparation and inoculation of anti-leprous serum.

Proceedings of the Society for Psychical Research. Part 32, Vol. XIII. July, 1897. London: Kegan Paul, Trench, Trübner, and Co. Pp. 282. Price 3*s.* 6*d.*—This book is an elaborate treatise on the use of the divining rod as a means of discovering underground water. The author, Mr. W. F. Barrett, Professor of Experimental Physics in the Royal College of Science for Ireland, states (p. 2) that it was with great reluctance that some six years ago he began to investigate the matter. Ultimately, however, he arrived at the conclusion (p. 24) that "the movement of the rod is not due to trickery nor any conscious voluntary effort, but is a more or less violent automatic action that occurs under certain conditions in certain individuals," and he became so convinced of the utility of the practice that if he had to sink a well he would (p. 240) "prefer to have the spot selected by a good dowser rather than general advice given by a geologist, provided that the depth of the well did not exceed, say, fifty feet." About 200 pages of the book are occupied with reports of the proceedings of various water diviners, dating for the most part since 1880. By far the greater number of the predictions were verified by subsequent digging or boring, but several failures as well as much adverse criticism by geologists are recorded. The very copious data collected by Professor Barrett will no doubt be appreciated by those who take an interest in this mysterious question.

Messrs. Raphael Tuck and Son's greeting and other cards and booklets for the forthcoming Christmas season are again up to the high standard of excellence for which their productions have been deservedly famed in the past. The interchange of pleasurable compliments is rendered the more delightful when they can be accompanied by souvenirs which may justly be termed works of art, and which will themselves be prized for their intrinsic worth apart from their sentimental value. Amongst so much which is so good it is difficult to single out any particular pieces for special mention, but the panel pictures, the Woodland Studies by Frank Hines, the Turner Portfolio, the Ryland Portfolio, and Yeend King's Four Studies by Brook and Meadow are especially worthy of mention. Nor are the children forgotten: there are many enjoyable pictures to amuse them.

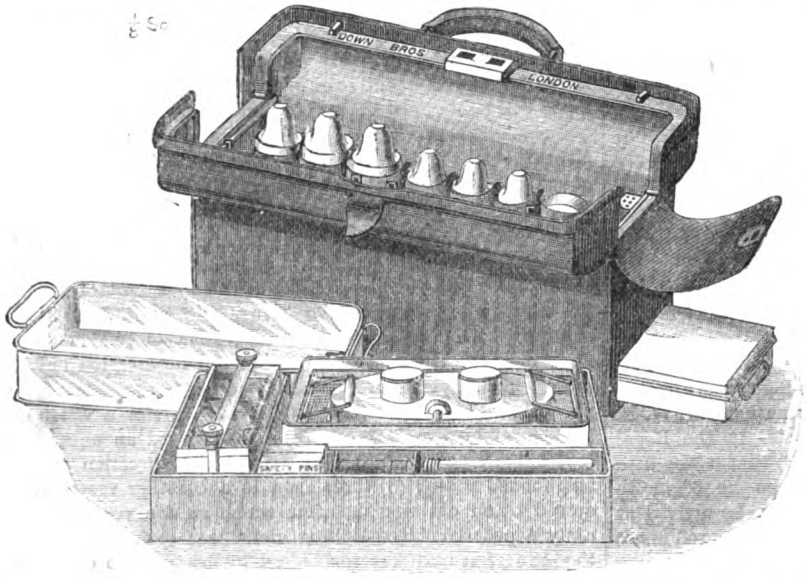
JOURNALS AND REVIEWS.

Practitioner.—In the November number Dr. H. D. Rolleston describes a puzzling case in which latent ulcer of the pylorus with jaundice simulated malignant disease. The patient was a man, aged twenty-seven years, who died ten days after admission to St. George's Hospital. Mr. Henry Strachan, senior medical officer of the Public Hospital, Jamaica, has an interesting paper on a form of Multiple Neuritis prevalent in the West Indies. The symptoms complained of are numbness and cramps in the hands and feet, dimness of sight, a tightness round the waist, and occasionally impaired power of hearing. The main nerves to the extremities are very tender on pressure especially the ulnar nerve, and along the distribution of their terminal filaments they may be tracked by lines of fine herpetic vesicles. Some of the nerves of special sense are also involved, principally the optic nerve, the affection of which is most frequently retro-bulbar. The muscles of the limbs will waste until the "claw" hand and foot are marked features. Recovery from all the symptoms is the rule. Mr. Strachan considers that the disease is due to the poison of malaria. There are three other original communications. The "Hero of Medicine" this month is Theodor Schwann.

Caledonian Medical Journal.—Dr. Alastair MacGregor, of Shepley, Huddersfield, continues in the October number his remarkable paper on Second Sight, the first part of which has already been noticed in THE LANCET of July 31st, page 258. He describes six cases, four of which were instances of death that came under the observation of his father, a clergyman in the island of Skye, the antecedent phenomena being as follows: (1) a woman saw a vision of her son falling over a rock; (2) a man heard an unearthly cry, twice repeated, proceeding from the direction of his neighbour's house; (3) three men in a coasting vessel were cursed by an old woman, after which as the vessel sailed away a peculiar, black-looking cloud was seen hovering in the air over it and was recognised by fisherpeople on shore as presaging disaster, which seems to have taken the form of an unaccountable murder; and (4) a woman saw a very brilliant light on a funeral pall, which was spread on a table, and in the middle of the light the image of her niece's face. Two of the other articles in the journal, entitled respectively the "Macbeths of Islay" and "Medical Heroes of the 'Forty-five," are historical and biographical.

The Monist.—Professor Ernst Mach, of Vienna, contributes an important physiological paper on the sensations experienced during rapid movement and change of position. It is headed "On Sensations of Orientation" and describes numerous observations made by Professor Mach on himself whilst seated in a rotating chair or lying on a board rotating in a horizontal plane. He considers that all the parts of the labyrinth are not auditory in their functions, but that the cochlea is reserved for sensations of tone and the semicircular canals for the sensation of rotation or angular acceleration, the nerves of the ampullæ being excited by the pressure of the fluid contents of the canal under the influence of inertia; he makes the further suggestion that the vestibule, particularly the portion of it known as the sacculus, is the organ of sensation of forward acceleration or of the position of the head. There are five other original articles.

WE are requested by the publishers, Messrs. Dawbarn and Ward, 6, Farringdon-avenue, E.C., to call attention to the fact that typographical inaccuracies appear in a book recently sent out by them for review entitled *Chemistry for Photographers*, by Mr. C. F. Townsend. The errors are being corrected. All persons who have obtained copies before Nov. 4th and who return them at once will receive revised copies in their place.



THE BRITISH ASSOCIATION.—At a meeting of the general committee of the British Association held in London on Nov. 5th Sir W. Crookes, F.R.S., was elected President for 1898, the vice-presidents being the Mayor of Bristol, the Bishop of Bristol, the Earl of Ducie, Sir E Fry, Sir F. Bramwell, Mr. J. Beddoe, M D. Edin., F.R.C.P. Lond., Professor Bonney, and Professor Lloyd Morgan. It was decided that the meeting in Bristol should be held on Sept. 7th, 1898.

New Inventions.

A SURGICAL BAG.

To the surgeon whose operative skill is in constant demand few things are of greater usefulness than a thoroughly well-made and serviceable bag in which to carry his instruments, dressings, sterilising apparatus, and ligatures.

The essentials of such a bag are: (*a*) strength and durability of material throughout; (*b*) simplicity of construction, especially avoidance of too numerous and complicated fittings; and (*c*) portability consistent with the two former essentials. Messrs. Down Bros. have given this subject much attention, and with a few suggestions from myself and others a bag has been evolved which admirably answers the purpose. The main features of this bag are: (*a*) on opening, an easily removeable tray with sterilising apparatus, a glass-covered and aseptic ligature-holder, drainage-tubes, iodoform dredger, and safety pins; (*b*) nail-brush and soap in metal boxes, and a few stoppered bottles in boxwood cases; and (*c*) a large space below for instruments, &c., with pocket inside, and at one end a small outside pocket with metal receptacle for dressings. Neatness and tidiness, scrupulous cleanliness, and minute attention to all details are invaluable qualities in a good surgeon, and to those who wish to foster and enlarge these qualities the surgical bag will be found an additional impulse for doing so.

N. HAY FORBES, F.R.C.S.Edin. (Exam.).
Drumminor, Tunbridge Wells.

REVERSIBLE CATHETER AND BOUGIE IN ONE.

WE have received from Messrs. Mayer and Meltzer, of Great Portland-street, a specimen of a new form of catheter. Each end of the instrument having an eye enables it to be used as a catheter or bougie. At will each instrument may thus comprise either two catheters or two bougies of the same form and size, and if the surgeon introduces either end alternately the instrument will last much longer than one of the ordinary non-reversible description. Again, each instrument may be a combination: one end of the instrument may be a catheter *à boule* or a bougie *à boule* and the other end may be a catheter or a bougie of the blunt-ended form. Two different sizes (as well as forms) may also be combined in one catheter or one bougie. The "reversible" instruments are made of rather greater length than those in general use, which provides for the contingency of one end of the instrument being rendered unserviceable through the eye becoming rough; and, moreover, if the reversible catheter is to be employed for washing out the bladder the surgeon has merely to remove one end with a knife and he then has an ordinary catheter of the usual length to which to attach tubing, &c. The instruments have the advantages that space is economised and that, as the catheters are solid-tipped, they are more readily dried internally after use, and are therefore less likely to deteriorate.

FIG. 1.

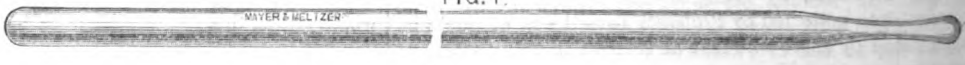

FIG. 2.

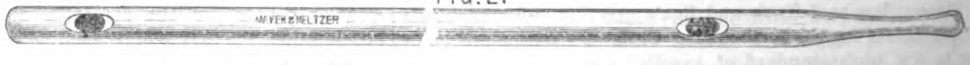

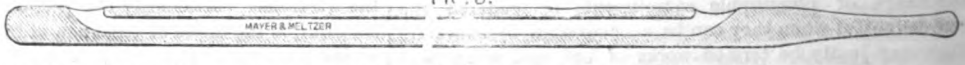

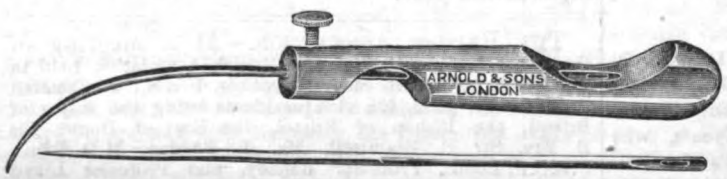

FIG. 3.

A NEW NEEDLE HOLDER.

I WISH to bring to the notice of the profession through the columns of THE LANCET a new needle-holder devised by Dr. Christian Branch and myself and manufactured by Messrs. Arnold and Sons. The advantages claimed for this pattern of holder are:—1. It can carry with equal facility a small suture needle or the long abdominal one. 2. Needles can be threaded with ease after being fixed in the holder before the introduction of the needle through the tissues. 3. It dispenses with the necessity, consequent on the use of a long needle with a handle, of being passed by one movement through the tissues, then threaded at the point, and, thirdly, drawn back; for one has only to loosen the screw and the needle, already threaded, can be drawn onwards by the other hand.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 13, 1897.

WE have had an opportunity of reading the report of the Sub-committee appointed by the British Medical Association to consider the question of advancing Army medical reform, together with its appendix. These documents have been prepared for the Parliamentary Bills Committee of the British Medical Association, and they not only furnish a comprehensive summary of the causes which have led to the present condition of the Army Medical Staff, but state the case of the medical officers very ably and lucidly. To discuss the whole subject fully would be tantamount to reprinting much of the report itself with a running commentary thereon, and that we cannot do. Nor is it necessary, for all who are interested in the matter are already familiar with the facts, while many of our readers have also studied the report itself and would not require to peruse its text again. It seems fitting and pertinent to the occasion that we should briefly allude here to the part which THE LANCET has taken in army medical reform. Very many years ago, when the so-called scheme of "unification" was in the air and its merits were being weighed in the scales with those of the regimental system, THE LANCET suggested and advocated the formation of a Royal Corps of Surgeons or Royal Medical Staff Corps, which should take its place with the other scientific branches of the service and be organised on lines analogous to those of the Royal Engineers, the medical officers retaining, of course, their then existing ranks and titles. The powers and functions of such a medical corps were to be strictly circumscribed within the limits of its legitimate duties and responsibilities. All that appertained to the care of the sick and wounded soldier and to the whole hospital service were to belong to it, while it formed no necessary part of the scheme that medical officers should not continue to do duty with their regiments. To a certain extent, of course, a medical journal holds a brief for the medical side of every question, but it should claim to advocate what will work for the dignity and well-being of the profession as a whole, and not of any particular section of it. We have always maintained that what is best for the public and the public services is best for the profession, and that every honestly contentious question should be frankly and fairly considered on its merits and not merely in the spirit of the advocate sympathetically and exclusively influenced in one direction.

With the greater number of suggestions in this report we are in cordial accord, and that they are reasonable—indeed, unanswerable—is attested by the fact that the War Office authorities have, we believe, already conceded a good many of them. It is ridiculous to suppose that young and highly qualified medical men of the present day will be content with what obtained in the past under very different conditions. The cost of the medical curriculum has greatly increased, and the medical profession is recruited from men of higher literary and scientific culture and a superior social plane than was formerly the case. The army should, it would be thought, attract its share of men of this higher stamp into its ranks, but it fails to do so—indeed, it fails to attract enough men for its bare needs in a time of comparative calm. The army medical service is seriously discontented, and as a consequence candidates for its ranks are few. It is not a question of pay, for medical officers are satisfied with their present rates of pay and pension. But man does not live by bread alone; and here we approach the crux of the matter. Medical officers urge, among other reforms, that the grant of army rank and military titles in a consolidated army medical corps is the most pressing need at the present time for the restoration of confidence and contentment. When the suggested organisation of a Royal Medical Corps was originally put forward, this question of purely military titles for medical officers had never arisen and would have been repudiated by the medical officers of that day. Great changes have taken place, however, since then, and there can be no doubt that a considerable majority of the medical service are in favour of welding together the Army Medical Staff and the Medical Staff Corps into a consolidated Royal Medical Corps to be officered by themselves under purely military titles. They maintain that this would be at once a reasonable and a comprehensive plan, and they allege a number of reasons why this should be done. Without attempting to enumerate them all, let us take some of them. Their real military rank and status, never altogether certain, were rendered most unsatisfactory by their having been some years ago deprived of relative rank, which was authoritatively stated to have had no real existence and to be a myth, while their present compound titles are confessedly cumbrous and complicated. A department carries less weight and meets with less consideration in the army than a corps. The only rank universally recognised in the army is army rank, and purely military titles have been conferred upon, and are used by, the Army Service Corps and the Pay Department. Medical officers are under discipline and amenable to the regulations and liable to be tried by court-martial; they serve in the field, accompany corps into action, and are exposed to an enemy's fire and to all the risks and dangers of war, in addition to encountering special ones of their own; hence they are and must be considered as soldiers and not as civilians: their functions and duties are composite, often very arduous and very responsible, and not by any means purely medical: and, lastly, it is urged that their experience both in garrison and in the field, and especially on war service, has taught them the essential need, if they are to carry out their work properly and satisfactorily, of having assured military rank and purely military titles, which are the only titles recognised in the army.

These points might be amplified, but such, briefly stated, is the ground taken up by medical officers. On the other hand, combatant officers make out a case something as follows:—If army surgeons desire to be designated by purely

Digitized by Google

military titles they have entered the army at the wrong portal and their titular distinctions are in reality false and misleading and somewhat inconsistent with the dignity and functions of the profession to which they belong. Their going under fire and sharing all our dangers unquestionably entitles them to share, as they do, in all the military honours and distinctions open to us, but there is a confusion of ideas in their reasoning. Going under fire in the fulfilment of duty and having a right to combatant rank are not by any means conterminous expressions. The whole *raison d'être* of the combatant officer is to command, fight, and kill, in order to defeat the enemy, whereas the *rôle* of the medical officer is to save life and succour the sick and wounded; it is for this that he has been educated, and for this he is specially paid. It is only occasionally and under exceptional circumstances that he has to depart from this *rôle*, and when he does so depart his combatant work is not his sole and special duty, as it is the sole and special duty of a general, captain, or subaltern officer. By all means give him military rank and power commensurate with his grave responsibilities and make his office and position as good and respected as possible, but this will never be done by conferring upon him titles which rightly designate our calling and not his. As regards the army surgeon's position, social standing, and the amount of consideration and respect and the personal regard in which he is held, he occupies exactly the same position in these respects that other officers do. If he is a gentleman and a pleasant fellow and interested in his work he is sure of every consideration, while it is not to be supposed that officers as a body are so oblivious of the interests of themselves, their families, and the soldiers under them as not to prize highly the advantage of having a good reliable man to look after them.

A good deal has been written and said on both sides of the question which was either irrelevant or had better not have been written or said. We have tried to put the two aspects of the case as fairly and dispassionately as we can in order that those of our readers who are not army medical officers may understand the respective views. It is obviously of the greatest importance that the army and navy should possess good medical officers and gentlemen, and that the army should offer such attractions as to secure a number of highly qualified men who are proud of their profession and desirous of succeeding in it by the exercise of their professional skill and attainments. Their duties in military life are, and must be, mixed—those of a soldier as well as those of a surgeon. The past traditions of the medical department are such as the whole profession may be proud of, and illustrations of zeal, bravery, and devotion within its ranks are constantly occurring in the present. We can only repeat that medical officers allege that the time has come when the possession of titular army rank is necessary for their position and the proper discharge of their duties. They ought to know best, and the reason is not clear why they should not be styled captain, major, or colonel of the Royal Medical Staff Corps. We trust that the War Minister will thoroughly consider all they have to say in regard to this and other matters in any action he may take. Lastly, the sooner some action is taken the better for the good of all concerned.

AMONG the many interesting and important subjects which were discussed at the recent meeting of the Association Française d'Urologie under the presidency of M. GUYON, there was none of more interest or of more importance than the modern treatment of hypertrophy of the prostate gland. The consequences of an enlarged prostate, such as retention of urine and consecutive disease of the kidney, may be so grave that for many years surgeons have been seeking for some method by which the hypertrophied prostate could be reduced in size. Urethral prostatectomy was first tried and elaborate instruments, built on the plan of a lithotrite, were invented, and these were intended to seize and tear off a portion of the gland and remove it by the urethra; but they were uncertain and of little value and were soon disused even by their inventors. The suprapubic operation then followed, in which the bladder was opened above the pubes, and portions of the prostate were removed by cutting or by gouging instruments; the results in some cases were fairly satisfactory, but the operation was by no means simple and the hæmorrhage was occasionally very profuse, so that the method was only employed in a comparatively few cases. The next attempt came from a new source. Pathologists have often compared the fibrous hypertrophy of the prostate to the fibromata of the uterus, and though the analogy is an entirely mistaken one, yet it has led to important results. It has long been the custom in certain cases to attempt to prevent the further growth of uterine fibromata by removal of the ovaries; then it was said, Why should we not endeavour to modify the growth of the prostrate by the analogous operation of removal of the testes? RAMM, of Christiania, and WHITE, of Philadelphia, almost at the same time and apparently quite independently of each other, proposed to perform castration as a mode of treating prostatic hypertrophy. They soon acted on the suggestion and found that after removal of the testes the prostate rapidly diminishes in size, voluntary power over the bladder is regained, and the patients are often much improved in health. Sometimes the improvement in micturition is exceedingly rapid, much too rapid for it to be due to organic changes in the substance of the prostate; in these cases it is probable that the relief is due to a shrinking of the prostate from a contraction of its vessels; but atrophy of the gland also takes place even to a remarkable extent in some instances. Yet in all cases the result is not equally favourable. In some the patient is rapidly restored to almost perfect health; these unfortunately form only a comparatively small portion of the cases; in others the improvement is slight at first, but as time goes on the power of micturition increases, though it may never be quite complete; in others the relief is only small, even after the lapse of many months, and in a large number the failure has been absolute. The mortality also after castration for prostatic hypertrophy is by no means small; it has been found to amount to 19 per cent., and though doubtlessly a large portion of this death-rate is to be attributed to causes other than the operation itself, as the patients are often in an extremely bad state of health, yet when full allowance has been made for this the mortality is remarkably

Digitized by Google

high. A form of violent delirium, sometimes permanent, has also been found to follow the operation in a few cases. CARLIER, of Lille, mentioned at the congress that the operation had been performed in more than five hundred cases; yet we have, unfortunately, no power of saying which case will be benefited by castration and which will not. Vasotomy, or division of the vas deferens for prostatic hypertrophy, was probably first performed by REGINALD HARRISON; certainly in some cases atrophy of the prostate follows the operation, but in very many cases it is an utter failure. It is by no means improbable, and the theory is supported by some experiments on the dog by ALBARRAN and MOTZ, that the atrophy of the prostate which follows vasotomy is really due not to the division of the vas, but to the division of the nerves and vessels of the cord, and "angio-neurectomy" of the cord with preservation of the vas deferens, has been suggested, and has been shown experimentally to be followed by as much atrophy of the prostate as occurs in cases where the whole cord has been divided. It cannot be said that either castration or vasotomy has been established as a perfectly satisfactory method of the treatment of enlarged prostate which is interfering with the outflow of urine. Each method in certain cases gives excellent results, but the failures are many, and with castration at least untoward results are by no means rarely met with. We must come to the conclusion that these methods which have been discovered for the treatment of a most obstinate and troublesome disease are valuable, but that we have yet to learn what are the indications for their employment with certainty of success. At the meeting of the Association Française d'Urology eleven papers were read on castration or vasotomy, and this fact shows how much attention is being directed to this subject at the present time.

IN THE LANCET of Oct. 9th (p. 928) we published a short annotation respecting an inquest that had recently been held at Twerton, near Bath, and we took occasion to compliment the coroner upon the way in which he conducted the investigation and to express the opinion that the verdict of the jury would receive general commendation. In our issue of Oct. 16th (p. 1008) will be found letters from Dr. PRESTON KING and Dr. WILLIAM H. COOKE reflecting on the course we had taken. We think these gentlemen have assumed more than the language we employed would warrant, and hence their strictures appear too severe. As, however, both letters contain most reasonable views on a topic of great interest to the medical profession and the public we think that it will be well to refer to them, even though to do so now has a somewhat belated air. As a matter of fact it can never be a belated action to discuss the subject of medical evidence at coroners' inquests, for it is one of abiding importance.

Dr. KING addressed himself in the main to two propositions: (1) that a second medical man who has not the advantage of having directly possessed himself of the facts of the case but has learned them from the testimony of others is fully competent to give scientific evidence as an expert; and (2) that cross-examination of medical witnesses should be allowed at the coroner's inquisition, as it is in the superior courts. We give an unqualified assent to each of these presentments, but as regards the first we would say that whilst the opinion of an expert witness founded upon facts related by others receives full recognition in proportion to the special knowledge and skill of the deponent, judges are ever and justly cautious in directing juries not to be misled, since there are two factors which tend to vitiate the formation and formulation of a judgment on facts procured in this manner. In the first place, the narration of facts may be faulty; and, secondly, there is the possibility of misinterpretation of what a witness conveyed or intended to convey. We would remind Dr. KING that the coroner's court is one of first instance; that hearsay evidence is to a great extent admissible; and that consequently procedure is not governed strictly by the "laws of evidence" as in the magisterial and superior tribunals. Consequently a special or expert witness is to some extent in the difficulty of not knowing the exact limitation of the facts upon which he has to direct his powers of reasoning. Moreover, the law relating to coroners' inquests does not provide for the cross-examination of witnesses by counsel; in fact, it is entirely within the discretion of the coroner to allow or disallow such method of investigation. This is a salutary provision, in our opinion, for many witnesses would fail to give full testimony of their knowledge if hampered by technicalities incidental to what must be considered as "hostile" examination by counsel.

Dr. COOKE'S communication is to some extent on the same lines as that of Dr. KING, but it touches upon important matters of forensic interest beyond the question of legal investigation. It may be remembered that the person upon whose body the inquest was held was found in a semi-conscious state near his own dwelling. He had a wound at the back of the head and less important ones upon the forehead, the pocket of his flap trousers was exposed, and his keys were found at some little distance from him. At the post-mortem examination made by Dr. HEATHCOTE the heart was found to be dilated and fatty and the organs generally congested. There can be no doubt, as Dr. HEATHCOTE said, that the deceased died from syncope, but another question of the highest importance was whether the cardiac failure had been determined by a blow or injury previously to the fall. Dr. HEATHCOTE, whilst not denying this, was of opinion that the facts on the whole were against this theory. The man stated before becoming unconscious that he had been assaulted. Dr. HEATHCOTE explained this by supposing that a sudden and unexpected pain in the head, or a cardiac pang coeval with cerebral anæmia and faintness, may have been wrongly believed by the deceased to be the result of external violence, and that therefore his statement was not worthy of credit. Dr. COOKE asks, If this were so would he almost in the same breath have accurately told the bystanders where his keys were to be found? We allow that this is both pertinent and relative to the issue. It fully warranted the jury in returning an open verdict as regards the incidence of a blow prior to the proximate cause of death. The fact that a £5 note known to have been in the possession of the deceased has not been traced is, moreover, suggestive of foul play. Clearly there is ample

Digitized by Google

reason for further police investigation. Whilst regretting that the coroner's inquiry should have led to a difference of opinion between the medical men, we see no reason to alter our previous statement—that the coroner is to be thanked for his painstaking care as are the jury for their logical verdict.

Annotations.

"Ne quid nimis."

IRRITABLE HEART AND TRANSIENT MURMURS AS A CAUSE OF REJECTION OF CANDIDATES FOR THE ARMY AND PUBLIC SERVICES.

IN the annual address to the North-West London Clinical Society delivered on Oct. 20th Sir William Broadbent dealt mainly with this subject. He alluded to the hardship which rejection on medical grounds entails upon the young man who has gained a place on the list for admission to Woolwich or Sandhurst and added, "In my judgment this has sometimes taken place on totally inadequate grounds." In illustration he mentioned cases of so-called "irritable heart," cases of bruits heard over various cardiac and pulmonary areas, and also cases of intermittent or cyclic albuminuria, on account of which candidates may be refused their commissions. The candidate with irritable heart has usually been spending long and late hours in study, with restricted exercise and limited fresh air, and with possibly unlimited tobacco. He presents himself for medical examination in a state of extreme nervous excitement. His pulse is rapid and perhaps irregular, his cardiac impulse is violent and may be diffused, even beyond the right sternal border. Murmurs may be heard at one or more orifices and his respiration is short and hurried. He is referred for three or six months, but on again presenting himself before the same examiner the ordeal reproduces symptoms which have been absent in the interim, and he fails to pass. Sir William Broadbent pointed out the importance in such cases of considering the personal history, saying: "It would take a great deal to make me reject the captain of a football team of a large school. ..... Such disturbance of the action of the heart, however exaggerated, is not inconsistent with perfect soundness and efficiency." "A fair test" would be to make the man run a mile round one of the cinder paths at his own pace, noting his time, but especially the period at which he got his second wind, and how he finished up. Sometimes, he added, "a run up two flights of stairs would bring the heart to its senses." A more common cause of rejection is the presence of a murmur which may be perfectly innocent of significance. Such murmurs may simulate closely a soft systolic mitral, but are heard only during inspiration or when the chest is full, and are due to compression of the overlapping lung by the heart during systole. Pulmonary murmurs may depend on bulging of the conus arteriosus against the chest wall; they disappear when the lung is interposed on deep inspiration. Sometimes bruits are heard, not only in the course of the ordinary mitral regurgitant, but over the greater part of the lung. In such cases there is usually pleural adhesion. "I have known such bruits," said Sir William Broadbent, "to be looked upon as indicative of valvular disease, requiring treatment by digitalis and demanding all sorts of precautions in the matter of exercise," and he mentioned the case of an athlete, aged twenty years, who presented a murmur resembling the mitral regurgitant, and also one over the pulmonary area. Apart from the bruits the heart sounds were normal, and in particular there was no accentuation of the pulmonic second sound. The left side of the chest was narrower than the right and moved less on respiration. The condition was probably due to pleuro-pericardial adhesion, and after five months' very vigorous exercise the patient was none the worse. The criterion of pseudo-mitral disease is absence of displacement of the apex beat and of accentuation of the pulmonic second sound, or undue right ventricular impulse, together with absence of symptoms. Restrictions as to games in such cases, except with regard to football, house runs, and training for races, are often needlessly imposed. Other murmurs are heard in the tricuspid area which are perfectly harmless. And such tricuspid bruits are rarely constant. Sir William Broadbent also alluded to dilatation of the heart and intermittent albuminuria. Sir William Broadbent's address should be of great practical value, not only to the authorities on whose fiat appointments to our public services depend, but also to all practitioners who meet with the difficulty of diagnosing organic and permanent from functional and temporary disease.

SANITATION FOR HOPPERS.

THE Maidstone epidemic has, at any rate, had one good result—namely, that of calling attention to the grossly insanitary conditions under which hoppers are compelled to live during the ingathering of the hops. A special correspondent of the *Times* has been investigating the circumstances, and his letter on the subject reveals a state of things which we can only describe as disgraceful. With all our boasted and ruinously expensive system of education, our sanitary organisation, county councils, health boards, and the like, it appears that hops are gathered by a process which for total disregard of decency, sanitation, and cleanliness, to say nothing of the first principles of Christian charity, carries us back to the most immoral period of the eighteenth century. This being so, for a district to put up with the gathering ground of a hop-garden for its water-supply is to invite disaster. To begin with, hops are a very exhausting crop and the ground therefore requires constant manuring. Neither is the manure solely that of animals. Every kind of filth is employed—fish-offal, old woollen rags and waste, street sweepings, and the like are used; and water running off a gathering ground polluted with this sort of stuff is almost sure to be contaminated. But this is only the minor evil, it is the herding together of a mass of human beings, some of them of the very lowest class, under such circumstances as preclude the observance of the most ordinary laws of health which, does the mischief. It must be said that all the hopper houses are not equally bad, for the newer ones are built of wood with iron roofs and are portable; but even these are grossly overcrowded. There is absolutely no sanitary accommodation whatever, and this being so, says the *Times* correspondent, "the most dangerous of all pollutions takes place on the ground." The hop-garden itself is generally used for this purpose; and where part of the Farleigh supply arose the collecting pipes were only 2 ft. below the surface of the ground used by the hoppers. It must not be supposed that we object to house refuse, offal, or excrement being deposited in the fields. The fields are the best and most suitable place for such materials, and earth purification the cheapest and most thorough. What we do object to is the fact that such substances are deposited close to the gathering pipes of a water-supply which is sure to get fouled by these waste products before the kindly earth has had time to render them innocuous. Again, there is no water laid on to the hopper houses, the hoppers are not allowed to get it from the farmhouses, but have to do so where they can. And yet water is laid on to nearly all the hop-gardens themselves. It would be easy to put up

Digitized by Google

a stand-pipe and so ensure a clean water-supply, but this is not done. It would appear that the primary cause of these horrible abuses is, as in so many other commercial enterprises, the high-pressure race for wealth. In some of the hop-gardens the gathering of the hop-crop is a kind of village festival, there are no imported hoppers, and the result is a small return to the farmer. But in the neighbourhood of Maidstone "it is a great money-making concern, in which the imported hop-pickers are but part of the machinery and of somewhat less account than the rest." Epidemics are hard masters, but possibly the sufferings through which Maidstone is passing will bring about a sincere reform of the present system of hop-gathering. If it is impossible to carry out the harvest on the lines on which it is worked in some places it should be made absolutely compulsory upon the grower to provide a proper supply of water, proper sanitary accommodation of the nature of a latrine, and housing at least as good as that of a stable or a kennel for hounds, and overcrowding should be absolutely forbidden. We suppose we shall be accused of interfering with legal commercial pursuits, but the wholesale poisoning of a neighbourhood is of more importance than the price of beer, and as at present excellent beer can be obtained from Maidstone for something under 2*d*. a pint it would hurt no one to pay 3*d*. for it, and no one would object if he had an assurance that by so doing he was furthering the cause of sanitation, to say nothing of that of humanity. It is right to say that in the *Times* of Nov. 9th appear two letters, one from the Principal of the Agricultural College at Wye, Mr. A. D. Hall, traversing every statement of the special correspondent, and the other signed "Spectator," which avers "that he is strictly within the limits of the truth." After this we may well ask, "What is truth?" and, unlike jesting Pilate, would stay for the answer. The *Times* correspondent maintains his attitude, and his words bear the stamp of accuracy.

BRAIN DESUETUDE.

SPEAKING at Selkirk on the 8th instant, Sir James Crichton-Browne dwelt on the dangers to health involved in indolence and disuse of the brain. The medical profession, he said, adapting itself to the needs of the times, had felt it incumbent upon it during the last decade to insist mainly on the evils of misuse of the brain, on the excessive strain not seldom imposed on it in these days in the fierce struggle of the race to be rich, and more especially on the over-pressure imposed on it in the name of education when in an immature state, but they were not less keenly alive to the correlative evils of the disuse of the brain. Elderly persons who gave up business and professional men who laid aside their avocations without having other interests or pursuits to which to turn were in many cases plunged in despondency or hurried into premature dotage. He did not know any surer way of inducing premature mental decay than for a man of active habits to retire and do nothing when just past the zenith of life, and, on the other hand, he did not know any surer way of enjoying a green old age than to keep on working at something till the close. It had been said that one of the rewards of philosophy was length of days, and a striking list might be presented of men distinguished for their intellectual labours which they had never laid aside, who had far exceeded the alloted span of human life. Galileo lived to seventy-eight, Newton to eighty-five, Franklin to eighty-five, Buffon to eighty, Farraday to seventy-six, and Brewster to eighty-four years. Sir James Crichton-Browne drew special attention to the great age generally attained by our judges. Our judges were, he said, men who could never fall into routine, but were called upon, as long as they held office, for mental effort in considering and deciding on the new points and cases which were constantly submitted to them. For the most part they had at one period of their lives undergone some over-strain in the active practice of an exacting profession, and yet they lived to a ripe old age, and were, he believed—notwithstanding the jokes and jibes of hungry aspirants at the bar—more exempt from dotage than any other class of the community. The sustained brain-friction in their case kept that organ bright and polished. These facts, he thought, ought to inspire us with some doubt as to the wisdom of the compulsory retirement and pension *régime* under which we lived. He had known several cases of mental disease induced solely by enforced idleness in men turned out of the public service, and more particularly the army, in conformity with a fixed rule, while still in the prime of life and capable of useful work. On entering the public service a man had to ascend by graduated steps of increasing work and responsibility. Was it not possible to arrange graduated steps of diminishing work and responsibility by which he might descend on leaving it? Much waste and wretchedness might thus be saved. The physiological notion of life was not cruel over-pressure at the beginning, penal servitude in the middle, and silly superannuation at the end, but the timely, continuous, orderly, well-balanced exercise of all the functions and faculties with which the being is endowed.

IMPORTANT DECISION AS TO AIR-SPACE IN COWSHEDS.

A VERY important case bearing on the question whether a regulation under the Dairies, Cowsheds, and Milkshops Order of 1885 enables an authority to specify a definite amount of air-space per cow in a cowshed has just been decided. The case is that of Baker *v.* Williams, and it was an appeal from the decision of the magistrates of Southport, which came before the court of Queen's Bench on Nov. 1st. The appellant, a dairyman, contended that a regulation as to air-space could not be made by the town council; that the word "ventilation" in the thirteenth section of the Order did not authorise any requirement as to air-space; that the provisions of no Act of Parliament authorised the Privy Council—now the Local Government Board—to make a regulation as to air-space; and that therefore the Dairies and Cowsheds Order was, in so far as the requirement as to air-space is concerned, invalid. The appellant's strongest point was that whilst in Sections 7 and 8 of the Order the words are "ventilation, including air-space," Section 13, under which the authority make their regulations, omitted the words "including air-space." But both Mr. Justice Wright and Mr. Justice Kennedy decided that in such cases the Order was in effect an Act of Parliament, that the Order and the statute must be read concurrently, and that consequently the authority had power to include the question of air-space when making a regulation in the matter of ventilation. It may be admitted that it would have been more satisfactory if the words relating to air-space had not been omitted from Section 13 of the Order, but it is most satisfactory that the decision is in the direction both of common sense and of the protection of public health. In cowsheds ventilation in its health aspect could not be obtained apart from a regulation as to a minimum amount of air-space; the two go necessarily hand in hand. And in so far as public health is concerned, it is notorious that the want of cubic space per cow, with its consequent crowding of cows together, is one of the most potent factors in conducing to bovine tuberculosis and to spreading that disease from cow to cow. The public as yet hardly realise the danger which children incur from tuberculous milk owing to overcrowding in cowsheds, but we hope some definite pronouncement on this point will be made by the Royal Commission on Tuberculosis, and that the report will contain a distinct condemnation of some of the regulations sanctioning insufficient cubic

Digitized by Google

space which some authorities have made. The amount of air-space upheld by the Court of Queen's Bench is 800 cubic feet in the present case, and this is the space which the Local Government Board recommend as a minimum. Unhappily, they cannot enforce it.

A GALLANT DEED.

IT is gratifying to learn that Major-General Yeatman Biggs has brought to the notice of the military authorities in India the gallantry of several of the medical officers who distinguished themselves in the action of Uhlan Pass on Aug. 27th last. Among them Surgeon-Captain Beyts has been signalled out for special mention, and his heroic conduct will add still another name to the list of those who at the call of duty have not hesitated to face almost certain death. After attending to the wounded under a heavy fire Surgeon-Captain Beyts, regardless of all consequences to himself, carried the body of Lieutenant North, who had been wounded, down a hill track too steep for a dhoolie, saving the life of the young officer who had become faint and powerless from loss of blood.

THE PAYMENT OF CORONERS' JURIES.

THE debate upon this subject having its origin in the report of the Public Control Committee of the London County Council, to which we referred last week, was resumed on Tuesday last. Sir Henry Poland pointed out that as it was usual to summon twenty-three jurors, and as the payment of only fifteen was provided for under the scheme of the committee, it would be better that the committee should take the matter back for consideration. Mr. Cornwall coincided in this view, on the ground that the suggested payment was inadequate. He said that it was a curious fact that those who could really afford to give their time were usually asked to serve on juries to which a fee was attached, while working men, of whom coroners' juries were largely composed and who should be fairly recouped for consequent loss, received no fee. The report was withdrawn for further consideration, but we hope that the matter will not be allowed to rest.

THE RINDERPEST.

APART from its economic importance, which is great, rinderpest, the extensive epidemic amongst cattle in South Africa, is of extreme interest to the pathologist; and at the Cape a very determined attempt is being made to control the spread of, and the mortality from, the disease by the very latest methods of bacteriology. Attempts to fence off the contagion by forming immense "belts," though for a time successful, ultimately failed to prevent the introduction of the disease. Destroying infected animals was of no more value, and then other methods were employed. The serum method, the bile method, and the glycerinated bile method have all been tried in turn. The objection to the serum method was the large amount required to ensure permanent immunity. The bile treatment certainly conferred immunity for a time; but it was accused of conveying the disease in some cases, and only certain biles could be used. Dr. Edington's glycerinated bile was introduced to obviate these objections, and it was to a very large extent successful, but the immunity conferred, though complete while it lasts, is very short-lived. It may last only twenty days or, as some say, two or three months, but after the lapse of that time the animal is very liable to be attacked if in an infected area. Other expedients are almost daily being suggested and tried. One of the latest methods is that advocated by Dr. Danysz and Dr. Bordet. They consider that true permanent immunity can only result from an attack of the disease; they inject into the animal some "salted" serum and then allow the beast to mingle with infected cattle. Immediately after the injection the immunity is complete, but in a few days the efficacy of the serum injection has diminished sufficiently to allow the animal to take the disease, but the attack will be very mild because of the remaining protective influence of the serum. The method is ingenious and deserves thorough trial, and we may hope that one outcome of this severe epidemic will be that a satisfactory method will be devised of preventing such direful results in the future. In the present number of THE LANCET we publish an article from a correspondent in South Africa which gives a very clear account of the disease and the means employed to combat it. One other point of interest we may mention, namely, that the flesh of oxen dead from rinderpest is said to be perfectly harmless to human beings when taken as food, even if not thoroughly cooked.

THE SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT the meeting of the Fellows and Members of the Royal College of Surgeons of England which will be held at the College on Thursday afternoon, Nov. 18th, a resolution will be proposed on behalf of the Society of Members to the effect that the meeting repudiates the claim put forward by the Council in their resolution of March, 1896, to represent "the Members as well as the Fellows," and again calls upon the Council to accord the franchise to the Members. A second resolution will ask the meeting, "in view of the widespread public and professional evils induced by medical aid associations and other companies trading in medical attendance," to call upon the Council "to make a clear pronouncement for the information of Fellows and Members that the acting as paid servant of any persons who tout and canvass for patients or who allow the well-to-do classes to take advantage of rates of payment arranged to meet the necessities of the poor is 'disgraceful in a professional sense' and deserving of censure."

MR. PICTON ON THE VACCINATION QUESTION.

WE have never understood Mr. Picton when writing on the vaccination question, and he has now become more unintelligible than ever. Thus he wrote to the *Times* on Nov. 4th to make two assertions. One is a definite declaration to the effect that he entered on the inquiry made by the Royal Commission on Vaccination "with a belief in Jenner's alleged discovery." All we have to say on this point is that his questions at one of the first sittings of the Commission were directed to show that because in years where there i an increase in the number of vaccinations there is an increase in the number of cases of small-pox (a statement which requires qualification), therefore vaccination may be assumed to cause small-pox. It does not seem to have occurred to him that he was putting the cart before the horse, and that, as at Gloucester, the anti-vaccinationists get afraid of their neglect when small-pox becomes epidemic and rush to the vaccination stations, and so increase the number of vaccinations. Other people have been puzzled besides ourselves by Mr. Picton's assertion that he had been a true believer. M.D. reminds us in the *Times* of the 9th inst. that Mr. Picton wrote in 1889, the very year when the Royal Commission was appointed, to say that he "was rapidly approaching" the conclusion "that vaccination is of no use." So much for his declaration of his faith when he became a member of the Royal Commission in 1889. His second assertion is more astounding; it is that "seven years' study" on that Commission "at once" convinced him that "vaccination is absolutely futile." And yet at the end of those seven years Mr. Picton, not content to sign the general report, made announcements, together with Dr. Collins, in a separate report, in exactly the opposite

Digitized by Google

sense. Thus he put his signature to sentences such as these: "While shortly after vaccination there may be a certain amount of immunity or antagonism to the influence of renewed vaccination, *or inoculation with small-pox*,[1] ..... this soon wears off, perhaps more rapidly in some than in others." Then, again, Mr. Picton, once more associating himself with Dr. Collins's views, writes in the report of the Royal Commission: "Even if vaccination were a more effective and trustworthy prophylactic than we hold it to be ....." Here after seven years of study is a complete admission that Mr. Picton did believe vaccination to be of some value, and that he did not believe it to be "absolutely futile." It has been suggested before this that Mr. Picton has never yet mastered the elements of this subject of vaccination in relation to small-pox, and this is the most charitable view to take of his recent assertions.

A DEATH FROM CIGARETTE SMOKING.

WE extract the following paragraph from the lay press:—

"At Felling, near Gateshead, yesterday, at an inquest on the body of James Francis Duffy, aged sixteen years, the jury found that the lad died from syncope, due to nicotine poisoning, caused by the excessive smoking of cigarettes. Mr. Graham, the coroner, said there seemed to be quite an epidemic of such cases. It was time the attention of parents was called to the danger of their children smoking at so early an age."

We quite agree with the coroner, and would add, having regard to some remarks on the quality of cheap cigarettes which we were moved to make last week, that it would be very interesting to have an analysis made of the tobacco which formed the favourite smoking of this unfortunate boy.

A WELL-KNOWN POLICE SURGEON.

WE regret to have to record the death of Mr. George Bagster Phillips, M.R.C.S. Eng., L.S.A., who has been surgeon to the Whitechapel or H Division of Police for over thirty years, and who died on Monday, Oct. 27th, from apoplexy. A personal friend of Mr. Phillips, who was for some time his assistant, sends us the following brief communication concerning him: "The old proverb that a straw can tell the way the wind is blowing holds good if we look for Mr. Phillips's name in the Medical Directory. We there find exactly two lines about him, setting down simply his address, and his qualifications with their dates. This was typical of the man, for anything of the nature of self-advertisement was utterly abhorrent to his nature. Though he was one of the leading police surgeons in London, and was greatly trusted and respected by all the police authorities, he did not even mention his connexion with Scotland-yard, while he makes no allusion to the clubs of which he was medical officer and the members of which trusted him implicitly and regarded him with veneration. I was one of his assistants and learned a lesson that all my predecessors and successors could have learned, and doubtless did learn, from him in his quiet house in Spital-square—the lesson of doing all that had to be done to the very best of our ability without expecting any recognition of our efforts, the work to be done for the love of our profession and for its own sake. ..... Under a brusque, quick manner, engendered by his busy life, there was a warm, kind heart, and a large number of men and women of all classes are feeling that by his death they have lost a very real friend." Mr. Phillips's name became prominent in connexion with the series of crimes which took place in the Whitechapel district some years ago, and which are now popularly known as the "Ripper Murders," having conducted the necropsies on the mutilated bodies of the victims in conjunction with Mr. Bond. In this connexion it is well to remember that the crimes committed by people afflicted with what is technically known as "sadism" are at the present time affording particular danger to the community, several recent tragedies having probably had their origin in sadistic impulses. The individual thus afflicted may be in other respects perfectly sane, and when the desire for lust and cruelty comes upon him he commits his terrible crimes with so much secrecy and ingenuity that he frequently escapes detection altogether. The victims of sadism perform acts which vary in their monstrosity, but they generally proceed upon the same lines, and on inquiry into their antecedents they will nearly all be found to spring from a neurotic stock; in various members of the family will be found some pronounced insanity, hysteria, or other neuropathic condition, while the patients themselves frequently present some obvious cranial defect in formation, and many of them from youth upwards have exhibited a taste for cruelty to animals. This propensity in children should be carefully watched, and if the tendency persists in spite of every endeavour to turn the mind into healthy and humane channels some strong and early control should be placed over them or they may become a great danger to those about them—and not only, as is generally supposed, to those of the opposite sex. In a recent case in Islington the victims, for example, were of the same sex as the perpetrator.

[1] The italics are ours.

SEPTIC IMPETIGO.

A CASE recently communicated to the Société de Biologie in Paris by Dr. Triboulet[1] is interesting as affording an example of rapidly fatal impetigo due to the bacillus pyocyaneus. The patient, an infant aged ten months, was also the subject of acute miliary tuberculosis. Which of these diseases was chiefly accountable for the fatal result is, of course, uncertain. Dr. Triboulet considers that it was the former, and he alleges in support of this opinion the fact that sudden death is not exceptional in generalised impetigo, while tuberculosis as a rule does not kill with the same rapidity. In his case the bacillus was discovered in the fluid exuding from small ecthymatous ulcerations in the skin, and also in the blood of the heart, and in the liver and kidneys. Its identity was confirmed by cultures in beef-tea, &c., and by experiment on living animals. It was found, moreover, to exist as a saprophyte in the neighbourhood of the Trousseau Hospital, where this case occurred, having been discovered by one of the resident physicians on the bark of an adjacent tree. The facts of this case are obviously suggestive in relation to the occasionally surprising virulence of some skin eruptions.

[1] Journal de Clinique et de Thérapeutique Infantile, Oct. 28th, 1897.

THE CHAIRMAN OF THE LIVERPOOL HEALTH COMMITTEE ON THE HEALTH OF LIVERPOOL.

AT the final meeting of the Liverpool Health Committee for the municipal year the chairman (Alderman Cookson) gave an interesting review of the work of the Health Department during the past year. He instanced how greatly the work of the Health Department had increased of late years, as shown by the number of houses erected in 1897, which amounted to 1814, as compared with 474 houses erected in 1894. The general sanitary condition of the city during the first six months of the year was very satisfactory, the rate of mortality having been during that period 22 per 1000, indicating that the improved condition of the previous year had been fully maintained, each district in the city sharing in the general improvement. The sanitary horizon was, however, darkened during the third quarter of the year by the large amount of diarrhœa occurring amongst the children of the poorer classes, more especially in the case

Digitized by Google

of very young infants, a large number of which cases were due to the carelessness of parents in the neglect of the sanitary precautions persistently impressed upon them by the officials of the Health Department in the matter of feeding and attention to general cleanliness. With the single exception of this disease all the zymotic diseases had shown a satisfactory diminution. Typhus fever still lingered in squalid areas of the city, the deaths due to which amounted to 17, against 26 during the previous year. Not a single death was due to small-pox. A remarkable diminution in the number of deaths from typhoid fever occurred during the first nine months of the present year, which reached 76, as compared with 107 during a similar period in the previous year. With regard to this disease it had again been proved that food had been the medium of infection, close upon 30 patients having been infected by eating ice-cream which it was found had been manufactured under conditions which admitted of no doubt as to the source of contamination. The proposed clause in the Liverpool Improvement Act for licensing itinerant vendors and registering premises where food disposed of by them was manufactured or stored would be of unquestionable benefit. Great benefit had accrued by the amount of street-washing which was constantly taking place, and stress was laid on the injury to public health caused by rubbish and litter being thrown into the public thoroughfares, which under the Liverpool Improvement Act was a punishable offence. The birth-rate of the city had continued to be high, and in the older parts of the city reached 37 7 per 1000, while in the added and more aristocratic areas a lower rate prevailed—viz , 24·9 per 1000.

BOARD SCHOOLS AND MEASLES.

MEASLES is a disease which is apt to be thought lightly of, but it is making its importance felt very unpleasantly in two ways—first by its fatality and secondly by its interference with attendance at board schools. The latter inconvenience has been brought almost accidentally to the notice of the medical officer of health of Islington. Not being a notifiable disease he does not receive information of it as he would of other diseases from medical men. But he is disappointed at not getting information of it from school authorities. He has narrated to his public health committee the way in which he came to find out quite casually that up to Friday, Oct. 22nd, no less than 99 children had been excluded from school either because they were attacked or lived in homes where there were cases. The regulations of the School Board require the medical officer of health of the district to be informed of the child's exclusion on account of symptoms of infectious disease. But they seem rather vague as to the particular officer who is to convey this information. Apparently the duty devolves upon the head teacher. This doubt ought not to exist a single day longer, and we feel sure that the medical officer of the School Board will be glad to see that more precise instructions are given. Undoubtedly, as the medical officer of health of Islington says, the sanitary authorities do much for the health of board schools, and it is but fit that the authorities of the board schools should facilitate the efforts of the medical officers of health in minimising the evil of the spread of infection which seems so much to attach to the board school system. Apart from the mere local incidence of measles, its gravity as a cause of infantile death is becoming more and more serious. In London in the week before last the deaths from measles, which had been 19, 41, and 48 in the preceding three weeks, further rose to 58, or 20 above the average, and far exceeded the deaths (39) from both scarlet fever and whooping-cough. This is a state of matters that calls for the serious consideration of the Local Government Board. In well-ordered private practice measles in this country is scarcely ever a fatal disease. Its fatality among the poorer classes is a matter of grave significance. The first step to any efficient remedy of the evil must be in early information being supplied to the health officers. The Board has its rules and it is for the Board to insist upon these rules being obeyed.

MAYORAL HONOURS FOR MEDICAL MEN.

UP to the time of going to press we have received the following names of medical practitioners who have been elected to the office of Mayor: *Bootle:* John McMurray, M.D., M.S., M.A O., R.U.I. *Carnarvon:* Robert Parry, M.B., L.R.C.P. Lond., M R.C.S. Eng., L S.A. *Coventry:* T. Webb Fowler, M.R.C.S. Eng., L.R C.P. Lond., L.S.A. *Hastings:* Frederic Bagshawe, M.D. Camb., F.R.C P. Lond. *Hedon (Hull):* James Soutter, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A. *Henley-on-Thames:* James Lidderdale, M.R.C.S. Eng., L.S.A. *Marlborough:* James Blake Maurice, M.D. St. And., F.R C.S. Eng. *Ruthin:* Job Medwyn Hughes, M.B., C.M. Edin. *Saltash:* Robert Thornton Meadows, M.D., M.S. Edin.

MOTOR CARS AND HEALTH.

AS we have before pointed out, if motor cars should supplant vehicular traffic in our crowded towns the innovation would have an important bearing upon sanitation. Other and important possibilities of good from a health point of view suggest themselves if the experiment reported by the *Engineer* should prove successful. Says that journal:—

"A member of the Automobile Club de France has just had a steam house constructed to his order ..... in Paris. ..... The vehicle is in the form of a railway car, drawn by a Dion steam tractor of 30 horse power. It has a length of 7·70 metres and is 2·60 metres in width and height. ..... Entrance may be gained either by the folding doors at the side or by a door at the rear. Down the side of the car runs a corridor, with doors opening into the different rooms. The first room is used during the day as a salon, and at night as a sleeping-room, the transformation being effected by a couple of divans which may be turned down to form a bed 1·80 metre long and 70 centimetres wide. ..... Another room of the same size adjoining is to be used as a dining-room, and when not employed for this purpose the wooden partitions at the back and side may be folded up, thus making a large salon. There is also a lavatory and bath-room which will be fitted up with all the necessary accessories, and behind this is the kitchen, containing a cooking range, a cupboard for the utensils, and under the floor is a safe for the provisions. On the top of the car seats are provided for three or four persons, while here also are carried the supplies of water and coke. Enough combustible can be stored away, it is said, to last for a run of 500 kilometres."

THE SERUM DIAGNOSIS OF TYPHOID FEVER.

THE simple technique for the serum diagnosis of typhoid fever recommended by the Laboratory of the Board of Health for the Province of Quebec, which was started at Montreal and is under the bacteriological management of Dr. Wyatt Johnston, has been found after a year's trial to be quite satisfactory from a practical point of view. Dr. Wyatt Johnston has recently reported to the President of the Board of Health that he does not find quantitative work necessary for routine diagnosis, although for recording scientific observations quantitative methods must be selected. For the routine of official work he states that he prefers to employ cultures having a sensitiveness so low as to give no reaction at all with non-typhoid blood. Dr. Johnston wishes further to call attention to the importance of paying special care to the reaction of the test culture media. "Bouillon cultures," he writes, "showing after twenty-four hours' growth of typhoid at 37° C. a slight uniform cloudiness only and quite free from scum or sediment offer the greatest security against pseudo reactions. I find that

Digitized by Google

such cultures can be obtained by using bouillon just on the verge of litmus acidity, giving no blue whatever to the red paper. From 5 per cent. to 6 per cent. of normal alkali are required to make this bouillon neutral to phenol phthalein. Cultures which give a heavy bouillon growth are the ones which are most liable to give pseudo-reactions—i.e., to clump in a deceptive manner spontaneously or with non-typhoid blood. If the culture is too acid the reaction may be defective. With a proper culture I have never met with the typical reaction apart from typhoid fever."

A TESTIMONIAL TO DR. JOHN T. ARLIDGE.

SOME friends of Dr. Arlidge have proposed to form a committee for the purpose of presenting him with a testimonial of the high estimation in which he has been held for so many years by the profession and his friends generally as a practical philanthropist and sanitarian and as a literary man. The following have consented to have their names placed on the committee:—The Duke of Sutherland, Sir Samuel Wilks, Bart., F.R.S., Sir C. H. Gage-Brown, K.C.M.G., Sir Peter Eade, Dr. J. W. Ogle, Dr. Matthew Baines, M.D., Mr. W. H. Folker, Mr. T. W. Nunn, Dr. Lionel Beale, F.R.S., Dr. J. W. Moore, and Dr. Charles F. Moore, hon. secretary, 10, Upper Merrion-street, Dublin, by whom subscriptions will be received. Dr. Arlidge has ever taken a warm and active interest in factory operatives and has through a long life endeavoured to better the condition of the working classes. His services to medicine as editor of the *British and Foreign Medico-Chirurgical Review* also merit the recognition of the profession. We regret to learn that Dr. Arlidge is in failing health.

SOME OF THE RECENT SERVICES OF MEDICAL OFFICERS DURING THE BORDER CAMPAIGN.

WE need no apology for calling attention to the military despatches connected with the late operations at Malakand and the Swat Valley, for it is a source of real gratification and pride to notice the way in which the labours of the medical services generally and the devotion and gallantry manifested by several officers of those services have been specially recognised. In General Meiklejohn's despatch we read that Surgeon-Lieutenant J. Hugo, attached to the 31st Punjab Infantry, saved Lieutenant H. B. Ford from bleeding to death under exceptionally trying circumstances. Lieutenant Ford was wounded in a night attack and the wound involved an artery and gave rise to serious hæmorrhage. There were no means at the time of securing the vessel and Lieutenant-Surgeon Hugo had to compress the artery with his fingers for two hours, and subsequently on the following morning, while still compressing the vessel with one hand, managed to pick up the wounded officer with the other and carry him to a place of safety. Surgeon-Captain H. F. Whitchurch, V.C., is spoken of by General Sir Bindon Blood as having attended to the wounded under fire throughout the fighting during the relief and defence of Chakdara. General Meiklejohn, in his despatch dealing with the attacks from July 26th to Aug. 1st, in mentioning the medical staff says:—

Brigade-Surgeon-Lieutenant-Colonel F. A. Smyth was most zealous and performed his duties to my satisfaction. He volunteered to perform the duties of Provost-Marshal, and did so for a short time during the illness of Lieutenant H. E. Cotterill. The arrangements made by Surgeon-Major S. Hassan, senior medical officer, 38th Native Field Hospital, and the indefatigable attention and care with which he devoted himself to the wounded deserve great praise. The list of casualties is large, and Surgeon-Major Hassan has been untiring in his exertions for their relief. I hope his Excellency will think fit to consider his services favourably. Surgeon-Captain T. A. O. Langston, 38th Native Field Hospital, rendered valuable assistance in attending to the wounded under a heavy fire on the night of the 26th and each following night, and behaved with courage and devotion in carrying out his duties under very exceptional circumstances. Surgeon-Lieutenant W. Corr has worked night and day in the hospitals in trying to alleviate the sufferings of the wounded, and has most ably and efficiently aided Surgeon-Major Hassan.

We have already alluded to the gallantry exhibited by Surgeon-Captain Fisher in escorting two dhoolies to the assistance of Captain Ryder's company under a hot fire from the enemy when it was attacked near Badalai.

DISCUSSION ON THE PREVENTION OF ENTERIC FEVER AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

IN view of the recent disastrous epidemics of typhoid fever in Worthing, Maidstone, and other towns, much interest is likely to be taken in the discussion on the Prevention of Enteric Fever which has been arranged to take place at the next meeting of the Royal Medical and Chirurgical Society on Nov. 23rd. The council have made an excellent selection in asking Dr. Poore to open the discussion; and it is hoped that Dr. Seaton, Dr. Sims Woodhead, Dr. Macfadyen, Dr. Kanthack, and others will take part.

VACCINATION IN CYPRUS.

THE annotation which appeared in THE LANCET of Oct. 9th on "Small-pox in Cyprus," and which states that we had no information as to the condition of the population as regards vaccination, has been regarded by some as implying that vaccination is neglected in that island. We learn, however, from an authoritative source that this is by no means the case. A system of public vaccination was instituted in the island under the organisation of the late Dr. Barry, and it is believed that, taking the population as a whole, there are few people who are better protected against small-pox. Indeed, during the last fifteen years the average number of vaccinations performed annually has exceeded 5000 and most of these have been primary ones. The High Commissioner of the island, Sir Walter Sendall, K.C.M.G., was formerly associated with the Local Government Board in London, and we feel certain he may be trusted to see that in times of special risk every facility will be afforded to secure the re-vaccination of all persons needing such further protection.

LOCAL ANÆSTHESIA BY SCHLEICH'S METHOD.

THE endermic followed by hypodermic injections of weak solutions of sodium chloride were found by Schleich in 1891 to produce a certain amount of anæsthesia in the tissues treated.[1] He subsequently added to his solutions extremely minute quantities of various substances—e.g., cocaine, antipyrin, &c.—and found that he was thus enabled to produce a local anæsthesia sufficient for the performance of minor and even some major operations, without the infliction of more pain than resulted from the initial puncture of the needle of the injecting syringe. This he obviated by freezing the cuticle by means of an ether spray or chloride of ethyl. Since then Schleich has elaborated a careful system whereby his method of anæsthetic infiltration has been safeguarded from its first transparent dangers. He rightly insists that only a rigid following of the details of his instructions can ensure success. Dr. Simonson and Dr. S. Cohn, of Schöneberg, have recently published a paper in the *Berliner Klinische Wochenschrift* in which they say that they have employed Schleich's method in 102 operations with great success. They use ethyl chloride for the purpose of freezing the skin before the needle is

[1] See THE LANCET, Dec. 12th, 1891, p. 1338.

Digitized by Google

inserted. The painlessness thus induced gives courage to the patient, and even children will then allow cutting operations to be undertaken without difficulty. Dr. Brieglieb, also, writing in the *Zeitschrift für Praktische Aerzte*, is quite enthusiastic over the advantages of Schleich's plan, especially for country practitioners far from their professional brethren. He himself has performed many operations in this way, amongst others one in which he removed half the tongue for cancer. As soon as the operation was over the patient began to speak with the remaining portion of the organ, and got down from the operating table and into bed without assistance. In addition to the use of these injections or "infiltrations" for surgical purposes they are often most valuable in cases where pain from neuralgia, &c., has to be relieved. Cases are mentioned by Dr. Simonson and Dr. Cohn of both acute and chronic character in which the relief afforded has been most remarkable Success seems only obtained when the details of Schleich's plan are followed out with the utmost exactness.

INSTRUCTION IN TROPICAL DISEASES.

SINCE the delivery of Dr. Manson's address upon the necessity for improved teaching in tropical diseases sundry letters bearing on the matter have appeared in our columns and also in the lay press. The subject is no doubt of the greatest importance to a country like our own whose troops both naval and military, to say nothing of innumerable civilians, are employed all over the world, and we must allow that it would be an admirable thing if the other metropolitan hospitals and the great extra-metropolitan schools of medicine were to follow the example of St. George's Hospital and St. Mary's Hospital and institute a course of lectures upon tropical diseases. As regards the army we are not so badly off as, judging by the correspondence which has already appeared upon the matter, many people seem to think. For thirty-seven years tropical medicine has been taught at the Army Medical School, first at Chatham and afterwards at Netley, clinical material being afforded by invalided soldiers from India, China, and other tropical and sub-tropical stations in all parts of the world. All surgeons on probation for both the Army and Indian Medical Departments have to go through this course of Tropical Medicine, which lasts for four months, two or three lectures being given per week. The plasmodia of malaria are demonstrated to the surgeons, who are also taught how to search for, stain, and identify them. The amœbæ of dysentery are also studied as well as the bacteriology of plague and other tropical diseases. The first professor of military medicine was Dr. Morehead, I.M.S. and he was followed by Maclean, Boyes, Smith, Capley, and McLeod the present occupant of the chair. It is evident from this that the military and medical authorities at the War Office have not been so unmindful of their obligations with regard to this important subject as recent remarks upon the matter would suggest. With regard to the Medical Department of the Navy we see no reason why surgeons on probation for that branch of Her Majesty's forces should not be allowed, or perhaps we ought to say compelled, to attend the classes at Netley before, during, or after their time at Haslar, for although a knowledge of tropical medicine may be of slightly less importance to naval medical men than to those serving with troops on land they still see enough of the diseases in question to render instruction in them very desirable.

AT the opening meeting of the Epidemiological Society of London, which will be held on Friday, Nov. 19th, at 11, Chandos-street, Cavendish-square, the President of the society, Professor J. Lane Notter, will deliver an address on the International Sanitary Conferences of the Victorian Era.

A SESSIONAL meeting of the Sanitary Institute will be held at the Parkes Museum, Margaret-street, on Wednesday, Nov. 17th, at 8 P.M., Sir Douglas Galton, F.R.S., in the chair, when a discussion will take place on the Pollution of Water-supplies by Encampments of Hop-pickers, Casual Workers, and Tramps. The discussion will be opened by Professor W. H. Corfield, who will speak in reference to the dangers of pollution of municipal water-supplies, and Miss M. A. Chreiman, who will discuss the sanitary control of hop-pickers.

SIR WILLIAM BROADBENT, Bart., M.D. Lond., F.R.S., will preside at Sir Squire Bancroft's reading of Dickens's "Christmas Carol" at Portman Rooms on Nov. 22nd in aid of St. Mary's Hospital. This is the first of the series which Sir Squire Bancroft will give in London during the coming winter. Sir Squire Bancroft will also give a reading of the "Christmas Carol" in Bath on Jan. 4th in aid of the new chapel for the Royal United Hospital.

MR. WALTER SPENCER ANDERSON GRIFFITH, M.D. Cantab., F.R.C.P. Lond., F.R.C.S. Eng., Assistant Physician Accoucheur to St. Bartholomew's Hospital, has been elected President of the Medical Defence Union in place of Mr. Victor Horsley, F.R.S., F.R.C.S., Eng., who has resigned owing to his election upon the General Medical Council as one of the Direct Representatives.

THE Harveian Society of London will hold its annual dinner at the Café Monico, Regent-street, on Thursday, Nov. 25th, at 6.30 for 7 P.M. Members desiring to dine should communicate with the senior secretary, Dr. Cock, 1, Porchester Houses, W.

THE HOSPITAL REFORM QUESTION IN NEW YORK.

DR. FREDERICK HOLME WIGGIN recently read a paper before the New York State Medical Association entitled "The Abuse of Medical Charity," which proves that the abuses complained of in Great Britain have their counterpart on the other side of the Atlantic. He said that it was easy to demonstrate conclusively that as at present administered medical charity is demoralising to both the recipients and to the donor. Some idea of the alarming growth and extent of this evil might be obtained from the carefully prepared report of Dr. Stephen Smith to the State Board of Charity. Here it was shown that during the year 1895 837,971 persons applied for and received free medical treatment at 105 dispensaries in New York, that 1,418,847 free visits were made by these applicants to these dispensaries, and that 78,000 persons received free board, lodging, nursing, drugs, surgical dressings, and treatment. In other words, that something more than 49 per cent. of all the inhabitants of New York had claimed in one year to be unable to care for themselves. This should be contrasted with another statement by Dr. Smith to the effect that during the period from 1791, when the first dispensary was established in New York, to about 1870, the applicants for charity bore a ratio to the total population of 1·5 per cent. Dr. Wiggin then went on to quote from an editorial article in the *New York Herald* to show that Greater New York spent fifty millions of dollars every year on charities, and that, according to a conservative estimate, fully 50 per cent. of the donors' money was diverted from the purpose for which it was intended and was practically filched from the poor to whom it rightfully belonged. Again, according to one writer, Dr. J. B. Huber, there might be found in large numbers at dispensaries such people as actors, opera singers, gamblers, bar-tenders, policemen, farmers, prosperous business men and those owning houses, lawyers, and perhaps even a street railway president. According to another writer,

Digitized by Google

Dr. George F. Shrady, fully 50 per cent. of the applicants in the reception room of a well-known institution (which he dubs "the diamond dispensary") were well dressed, 10 per cent. were finely dressed, more than half the men bore no evidences of poverty, and among the women there was an attractive display of fine millinery, yet all obtained the free treatment supposed to be given only to poor persons. A reporter of one of the daily papers, in describing what he saw at a well known "clinic," stated that not more than one person in fifty was at all shabbily dressed, a large majority were fairly well dressed, one third of them were quite presentably dressed, and perhaps one-fifth were positively well dressed. Dr. Wiggin referred to the case of a man who paid an enormous rent in a fashionable apartment house near Central Park, and who spent many thousand dollars a year on living expenses, yet he went to what Dr. Shrady had so aptly termed "the diamond dispensary" on the plea that his expenses were so heavy that he could not afford to pay a fee to a medical man. "Surely," Dr. Shrady continues, these instances "show the spirit in which charity is asked for and accepted; it is largely a desire to save money without apparently thinking that self-respect is lost in the effort or that a wrong is done to the really poor and to the physician, who is certainly as much entitled to his hire as the clergyman or other members of the community, as he, too, has social obligations to fulfil." More than this, as Dr. Schweck had well said in the *Philadelphia Press:* "People of means who go to charity dispensaries and receive treatment free of charge, representing themselves to be too poor to pay for medical services, commit a criminal act, for they obtain what they are not entitled to, and do it under false pretences." Another and important aspect of this subject has been revealed in a communication from Dr. G. M. Roe, medical superintendent of the Boston City Hospital, to the *Boston Herald*. He says: "It is a generally accepted fact among people who have had large experience in doing charitable work that the first thing that a man or woman will accept as charity is medical attendance. They will accept free service of the doctor when you could not prevail upon them to accept rent or fuel or anything of the kind as a gift. The acceptance of gratuitous medical attendance is the first step towards pauperism. There is already a tendency towards what is generally known as 'nationalism,' a belief among the common people that the city and the State owe them a living, and that medical attendance, among other things, should be furnished them by common taxation regardless of their financial standing as individuals." Again, as Dr. J. J. Stevenson had expressed it in the *Mail and Express:* "If recovery from disease be secured at the expense of self-denial, the memory of the cost will lead in ordinary cases to care that a recurrence of disease and attendant expenses may be prevented. But if the careless feel that treatment, medicine, and even diet can be had simply for the asking, there can be no reason for resisting the natural tendency to neglect the laws of health. ..... It is not surprising that the reckless poor see in such careless giving an acknowledgment of the unequal distribution of wealth and believe that it is founded on injustice; nor is it strange that the anarchist's cry is not for opportunity to earn by labour, but for such distribution of wealth as may enable all to enjoy the luxury of idleness." The following are the conclusions arrived at by Dr. Wiggin after a critical review of the subject: (1) that medical charity as at present administered is an unqualified evil and is seriously menacing existing social conditions; (2) that the application for free treatment of those able to pay the physician a moderate fee for his services robs the really poor; (3) that all medical charitable institutions should be under the direction and control of State and local boards of charities, who should have the power to enforce their rules; (4) that all applicants for medical charity should be investigated by local charity boards, and the unworthy excluded; (5) that no medical charitable institution should be allowed to charge nominal sums for medical or surgical service, nor should they be allowed to charge for medicines or appliances; (6) that all physicians connected with charitable institutions should be paid for the service which they render; (7) that it should be made a misdemeanour, punishable by fine, for any person to receive free medical treatment by reason of false representations as to financial condition; and (8) that State or city aid should not be granted to private medical charities.

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

XIX.[1]

NEW RIVER COMPANY—*Continued.*

PRESENT CONDITION OF THE NEW RIVER.—A SURVEY (*continued*).

880 yards.—Hoe-lane. Here is a well and pumping station on the upper bank. Close to the Station is Hoe-lane Bridge.

440 yards.—Carter Hatch-lane bridge.

300 yards.—From this point for a distance of about a quarter of a mile the bottom and sides of the river are concreted, and the sides slope as 1 in 5. The river is about 5 ft. in depth at this point.

400 yards.—There is here a public foot-path on the lower bank for a distance of about 250 yards. The path goes from Enfield highway to Enfield town. Here, on the upper side of the river, pipes are being put to convey the surface drainage from the land. This work is being very efficiently carried out, and there are a large number of manholes to facilitate the cleansing of the drains. The course of the surface drain is shown in the map by a dotted line, the water is conducted in an 18-in. pipe under the New River at the point marked A 1 (Map 3).

200 yards.—Highway Fields foot-bridge. A new one is now being erected. At the part of the river which has been concreted an arrangement has been made to enable anyone who by chance should fall into the river to get out. At a distance of every 100 yards on each side there are three ladder irons, one above the other, placed in a recess. At points where public footpaths come next the river galvanised iron chains are to be suspended along the concrete walls, and this will be done in all those parts of the river which have concrete walls and which have also public footpaths adjacent. It is worthy of note that the New River is a private property, and that no one has any right to get into it. The Company is not under any obligation whatever to put up the iron chains or the ladders.

700 yards.—Enfield grate bridge.

50 yards.—From this point two 48 in. pipes take the water beyond Bush Hill sluice the course of the pipes being across gardens, under the Great Eastern Railway line, and then through fields. The river passes round the Enfield loop for a distance of about two and a half miles. Roughly speaking, half the water is conducted through the 48-in. pipes and the other half passes along the course of the river. The course of the pipes is shown in the map by a dotted line A 2 to A 3 (Map 3).

30 yards.—Station-road Farm bridge, Enfield. On the upper bank of the river here are market gardens. The river passes next Nag's Head-lane, which is a public road.

250 yards.—Enfield Station bridge.

200 yards.—Cherry Orchard-lane bridge. This part is fenced in on both sides except the last 40 yards, along which there is a path leading to the back entrances of some houses on the river bank. There is an occupation foot-bridge in the garden of a house in Baker-street.

200 yards.—Baker-street bridge. The river here has Enfield Court grounds on the upper bank.

450 yards.—Foot-bridge in Enfield Court grounds.

200 yards.—Occupation foot-bridge. Here a surface-water culvert passes under the river, going in the direction from the upper to the lower bank—that is, from the north to the south.

Pennefather's field.—Here there is a public foot-path.

300 yards.—Pennefather's foot-bridge; the public foot-path here comes from the upper to the lower side of the river.

60 yards.—Horseshoe bridge path. The public foot-path is here on the upper bank.

25 yards.—Occupation foot-bridge.

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., and XVIII. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th, May 1st, 8th, 15th, 22nd, and 29th, June 19th and 26th, Oct. 23rd, and Nov. 6th respectively.

Digitized by Google

20 yards.—Occupation foot-bridge.

40 yards.—Public foot-path from Chase Side to Enfield.

150 yards.—Chase Side foot-bridge.

130 yards.—Chase Side-road bridge. There is here a public foot-path on the lower bank as far as the foot-bridge at Carr's Basin. On the upper bank is Chase Park.

400 yards.—Carr's Basin and Carr's Island. Carr's Basin foot-bridge. Here the foot-path ends.

440 yards.—Seven Sisters grate bridge. Just at this point (7, Map 3) for a few yards the banks of the river are concreted in order to prevent any possible contamination from the weeds which are here taken out and left in heaps to decay.

200 yards.—Occupation foot-bridge.

120 yards.—London-road bridge. This is the high road from London to Enfield.

Waste Gate.—There is here a cogged sluice-gate 2 ft. 6 in. in width.

50 yards.—Occupation bridge. Manor House, Bush Hill.

200 yards.—Bush Hill Basin.

400 yards.—Bush Hill sluice house. Just below this house the water from the pipes returns to the river. It does not go through the sluice house, but enters the river just below the sluice. The sluice house is built across the river. Here there is an iron gate fixed in a cogged wheel and arranged with a balance weight. The gate is used to regulate the amount of water which is sent down the New River and instructions as to the amount required are received from the head offices of the Company. In this sluice house there are two gauge plates which record the height of the water above and below the sluice. The fall of the river at this point varies from 10 in. to about 2 ft. Just below the sluice house is Edmonton-road bridge, Bush Hill. Under the Edmonton-road there is an easement for the river—that is to say, it passes into two channels.

50 yards.—Foot-bridge, Bush Hill House.

220 yards.—Bush Hill House foot-bridge. It was here that the river was formerly carried over a valley in a wooden aqueduct supported on piles; later an embankment was made. This part of the river is now lined with concrete (Map 3, C C'). The channel is 24 ft. in width, 6 ft. in depth and the concrete extends for about half a mile. In Bush Hill Park the river passes over a brick arch. The arch was rebuilt in 1682 and under it there is a culvert which conveys surface water and an iron pipe for the sewage of Winchmore Hill, which goes to the Tottenham sewage works.

400 yards.—Bush Hill House occupation bridge.

250 yards.—River-bank Cottage bridge.

150 yards.—At this point an easement pipe 36 in. in diameter conveys the water to a point in the river 100 yds. lower down. This cuts off a loop (Map 3, D). Just opposite this point on the upper bank there is the beginning of another easement pipe. A pipe 6 ft. in diameter conducts the water for a distance of 60 yards; then for 300 yards the water is conveyed in a 4-ft. 6-in. pipe; then for a distance of 50 yards again in a 6-ft. pipe. The course of this easement is shown in the map. (Map 3, E E'.)

550 yards.—Occupation bridge, Ford's-grove.

3 yards.—Ford's-grove-road bridge.

50 yards.—Ford's-grove Farm bridge.

300 yards.—Highfield-row bridge.

150 yards.—Highfield. Here there is a well and pumping station on the lower bank of the river.

200 yards.—Barrowell-lane bridge. The bed of the river is concreted under the bridge and for a distance of about 10 yards above and below it.

550 yards.—Hedge-lane. From a point in the river about 20 yards above this bridge to a quarter of a mile below it the bed and sides of the river are concreted.

700 yards.—Hazelwood-lane.

100 yards.—Foot-bridge to Edmonton and Palmer's-green.

150 yards.—Here a culvert passes under the New River to convey the surface water from the western to the eastern side whence it flows into the Lee.

300 yards.—Starkey's-lane bridge.

200 yards.—King's Arms bridge. Here there is an easement. From King's Arms bridge the river runs on an embankment raised about 30 ft. above the surface of the land.

300 yards.—Arch above Pymme's Brook which takes surface water from Southgate, and discharges it into the Lee.

250 yards.—Cock-lane bridge.

350 yards.—Bowes Park bridge. Church path.

300 yards.—Bowes Manor foot-bridge (disused).

400 yards.—At this point the river enters Wood Green tunnel. Here is the junction of walks 3 and 4. The tunnel is built of bricks set in cement, the upper part is arched, the lower part is slightly inverted. The width is 12 ft., the depth 9 ft. For the greater part of a mile (1100 yards) the river flows in this tunnel.

The course of the Wood Green tunnel is under gardens between Myddelton-road, Bowes Park, and Truro-road, Wood Green, under Truro-road, Wood Green Urban District Council Gardens, then under Nightingale-road and the gardens of houses in Finsbury-road, under Commerce-road and a piece of land which formerly belonged to the New River Company but which has been lately given up to the Wood Green Urban District Council with a view to its being made into a public garden. From this point the canal passes under Trinity-road, a few yards of common land, Bounds Green-road, under another piece of land which it is hoped will be made into a public garden by the Wood Green local authorities, then under the Palace Gate branch of the Great Eastern Railway, across a public garden, under Park-avenue and for a few yards under another public garden, where the tunnel ceases and the water again becomes visible.

40 yards.—Station-road bridge, Wood Green. At this point the Wood Green Urban District Council public sewer crosses under the river in a 2 ft. pipe.

70 yards.—The river here passes under an arch of the Great Northern Railway main line. Close to the railway bridge is Hornsey grate bridge. The meshes of the grate are 4 in. and the bars 1 in. in diameter. A little below this point is Hornsey Basin. Hornsey Basin has an area of about an acre. It is 16 ft. deep in the centre. From it the Hornsey reservoir is fed through a 48-in. pipe guarded by a screw cock. Here are the Hornsey filter-beds and pumping station; and near by is the Campsbourne well and pumping station.

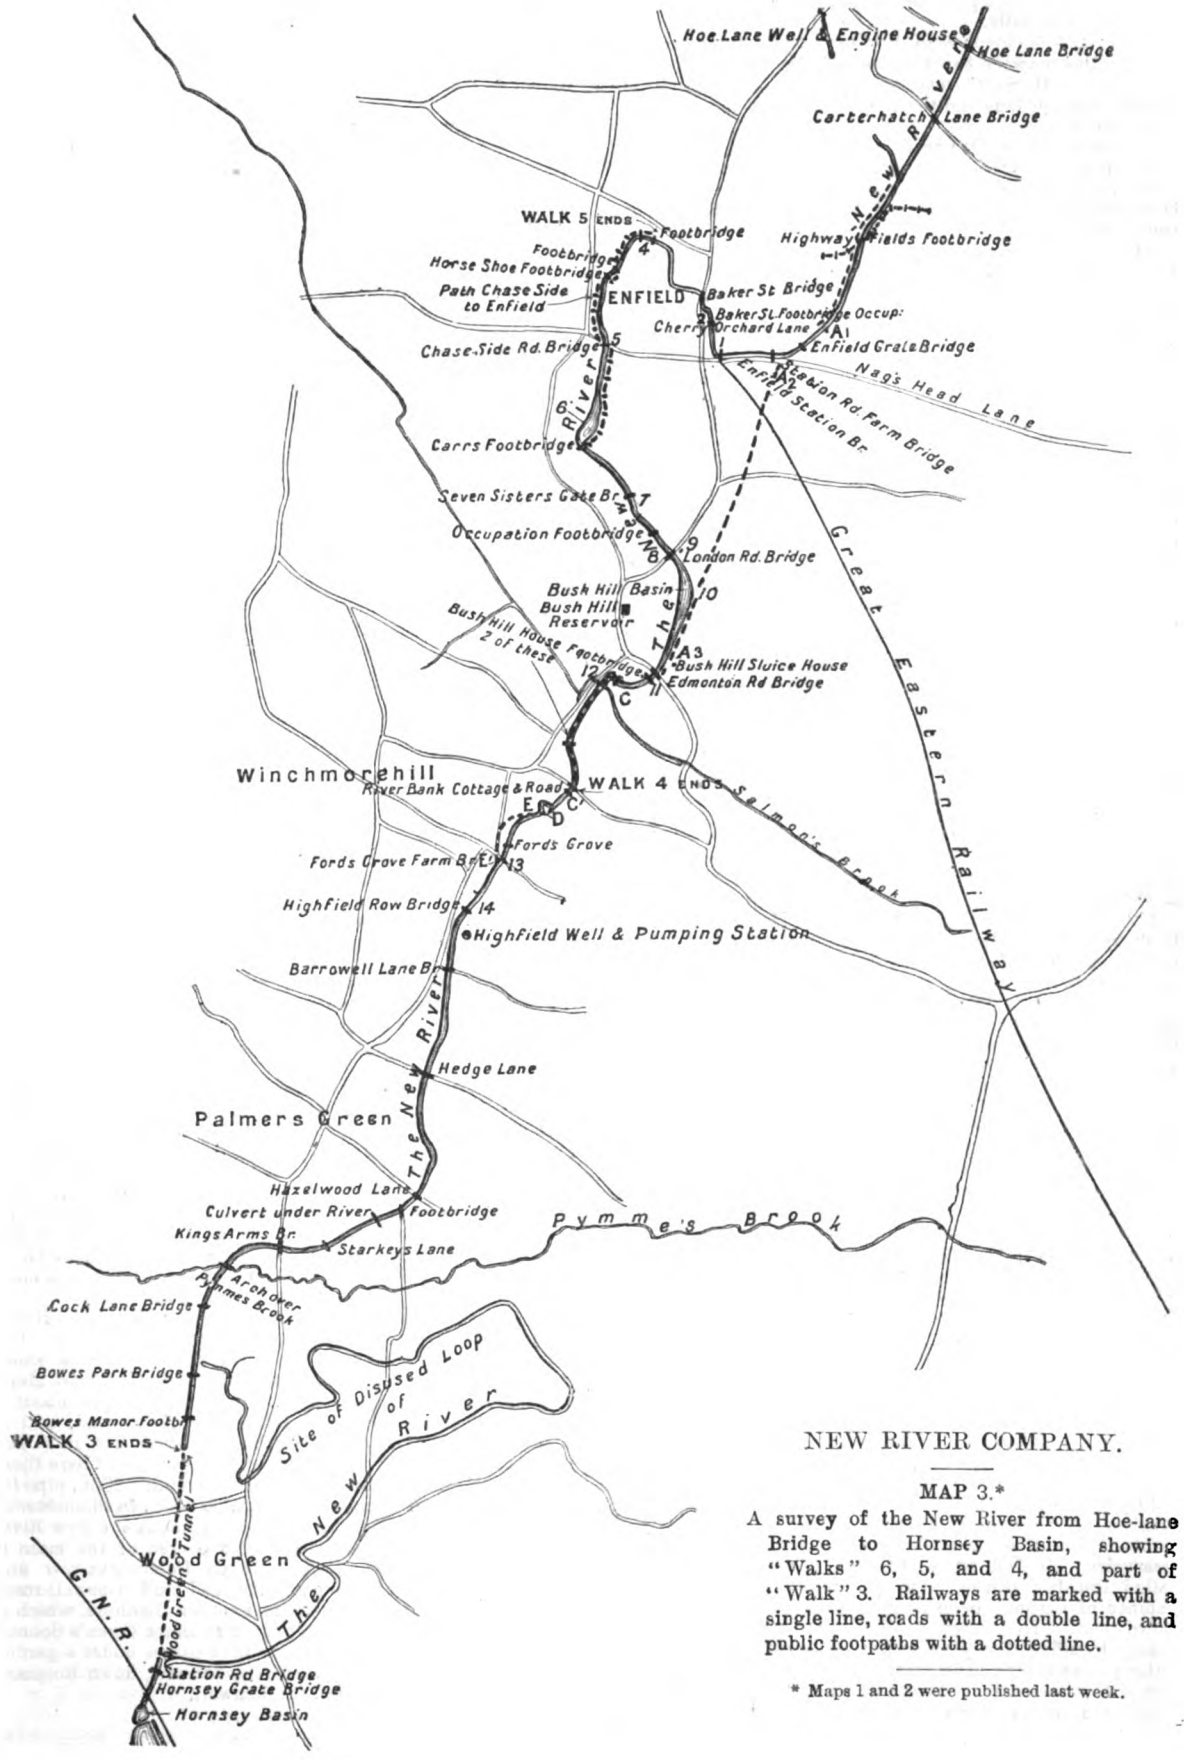
At Hornsey there is a floating boom and a sluice house across the river. The sluice-gate is 5 ft. in width and 8 ft. in depth. It is arranged with balance weights and worked by cogged gear. The house contains floating dial gauges, which, however, are not now used. Rack gauges are now in general use. A rack gauge, it may be stated, is an iron rod marked with notches 1 in. apart, and the rod is fastened to an oak pile which is fixed in the river. At this sluice there is a fall of about 3 ft. The amount of fall varies from a minimum of 7 in. to a maximum of a little over 3 ft. Formerly water was pumped from this station to Maiden-lane by a three-throw pump worked by an under-shot water-wheel. The wheel is not now in working order and the fall here is not at present used.

440 yards.—Tottenham lane bridge.

40 yards.—Great Northern foot-bridge.

300 yards.—Hampden-lane bridge. Here the Great Northern Railway is on the upper bank. This piece of the river for about a quarter of a mile is called the New Cut. It was made by the Great Northern Railway Company when their line was widened about twenty years ago.

400 yards.—Hornsey Urban District Council sewer passes under the river at a level of 20 ft. below the bottom of the river.



100 yards.—Here there is a shed for storing dam boards. These boards are 9 in. by 4 in. and are dipped in creasote.

15 yards.—Commencement of Harringay tunnel. This is guarded by a grating. Behind the grating there are two slots in the brick work; into these the dam boards can be fixed. The distance between the slots is 18 in., and this space can be filled with puddle. By this means all the water can be dammed back and the work can be very quickly done. This arrangement is used only when it is necessary to clean out the tunnel, an emergency which rarely occurs. The tunnel was made in the year 1891 and it has only been necessary to cleanse it once since that date. For emptying the tunnel of the water which it contains there is a cock pit made to receive it, and from this pit it is discharged into the sewers. The tunnel passes under the road which connects this part of the New River with Wightman-road. It then passes under the Wightman-road and under the gardens belonging to houses in Wightman-road and Hewitt-road. The course of the tunnel is then under Seymour-road, and it ends immediately after passing it.

100 yards.—Warham-road bridge. Here the river passes through a newly-developed residential neighbourhood and is skirted by back-gardens.

80 yards.—Pemberton-road bridge. There are gardens

NEW RIVER COMPANY.

MAP 3.*

A survey of the New River from Hoe-lane Bridge to Hornsey Basin, showing "Walks" 6, 5, and 4, and part of "Walk" 3. Railways are marked with a single line, roads with a double line, and public footpaths with a dotted line.

* Maps 1 and 2 were published last week.

Digitized by Google

down to the river on each side. Just beyond Pemberton-road the gardens are guarded on both sides by an iron fence which has four rails.

80 yards.—Mattison-road bridge. Here there are open iron hurdles between the gardens and the river.

90 yards.—Duckett's-road bridge. There are iron hurdles between the gardens and the river. One part is protected by a wooden fence.

90 yards.—Cavendish-road bridge. On the upper bank there are iron hurdles and a piece of spiked rail.

90 yards.—Burgoyne-road bridge. On one side the river is protected by a piece of oak fence and on the other by iron hurdles.

90 yards.—Umfreville-road bridge. Here the river is fenced by hurdles and wooden railing pointed at the top. There is also remaining a piece of the standard fencing which was formerly used all along the river.

150 yards.—Midland Railway. This is a branch from Tottenham to Hampstead. On the day before this part was visited there was a severe thunderstorm in the afternoon, and it rained very heavily for some time. The surface water from the sides of the railway collected in considerable quantity and covered the line, so that the traffic was for a time stopped. The water also overflowed a garden which is by the side of the railway and washed large quantities of ballast from the line on to it, and the water overflowed and ran into the New River. The man who had this piece of garden said that more than one such flood had occurred there during the last nine years. He stated, also, that at the early part of the flood the water which came down was much discoloured and had an evil smell; that it came from the surface water sewers at Crouch Hill which were liable to overflow after a heavy storm. The arrangement at present in existence for conducting away the surface water at this point is a 9-in. iron pipe which passes under the river, and this pipe is certainly of insufficient size to conduct away the surface water which collects after a heavy storm. The man whose garden was inundated during the storm said that during the period of heavy rain forty 9-in. pipes would not have been sufficient. This may possibly be an exaggeration, but be this as it may the present arrangement for the conveyance of surface water is obviously inadequate.

Midland Railway bridge.—Here is the junction of walks 3 and 2. Here the lower bank is open; the upper is guarded by a standard fence.

150 yards.—Endymion-road bridge. Here, on the lower bank, is Finsbury Park. This is the part which is used for playing cricket. It is divided from the New River path by a high fence.

100 yards.—Finsbury Park bridge. At this point the entrance of the path by the river is guarded from the road only by a low oak fence, so low that children can get on to it and sit on it without any trouble. Between the path and the cricket-ground there is a high wire fence, and on the upper path the standard fence between the path and the river. The day before this was visited after the thunderstorm the New River here overflowed into the cricket-ground. This is said to be a rare accident.

300 yards.—Northumberland bridge, Green Lanes. Here, on the upper bank, is situated Northumberland House Lunatic Asylum, the grounds of which extend for 500 yards along the bank of the river.

100 yards.—Northumberland House foot-bridge. This bit of the river goes along the hillside, the upper bank sloping gradually down to the river, and there are here some very good gardens which go down to it.

800 yards.—Seven Sisters-road bridge.

300 yards.—Woodberry Down bridge. There is here a foot-path which is public, but the bridge is made for carriages and there is a bar at the end which is kept by the New River Company. The public drive to the houses is from Seven Sisters-road.

30 yards.—Stoke Newington grate.

40 yards.—Here is the Stoke Newington Station, which consists of reservoirs, filter-beds, and pumping arrangements. The river now flows along the north side of the reservoirs. It first passes through a disused sluice house called the Ivy House. On the upper bank there are a number of gardens belonging to houses in the Woodberry Down-road. The water in this part of the river is only changed sufficiently often to keep it sweet. Almost all the water passes through the reservoirs. The distance along the first or east reservoir is about a quarter of a mile. From this point the water flows from the western end of the reservoir and is conducted for a distance of about twenty yards in the river, which passes under Lordship-lane bridge. Most of the water goes into the west reservoir, which is situated on the lower bank, and the sluice which admits it is situated at a distance of about 100 yards from the road. The river now flows along to the north of the west reservoir, and at a distance of 600 yards lower down the water which has been in this reservoir comes again into the river. Into this piece of the river, like that next the east reservoir, only enough water is allowed to pass to keep the river sweet. Almost all the water passes through the reservoir.

30 yards.—Newington grate bridge. Here is the pumping station.

50 yards.—The river passes into a 54-in. pipe and goes down the course of the Green Lanes.

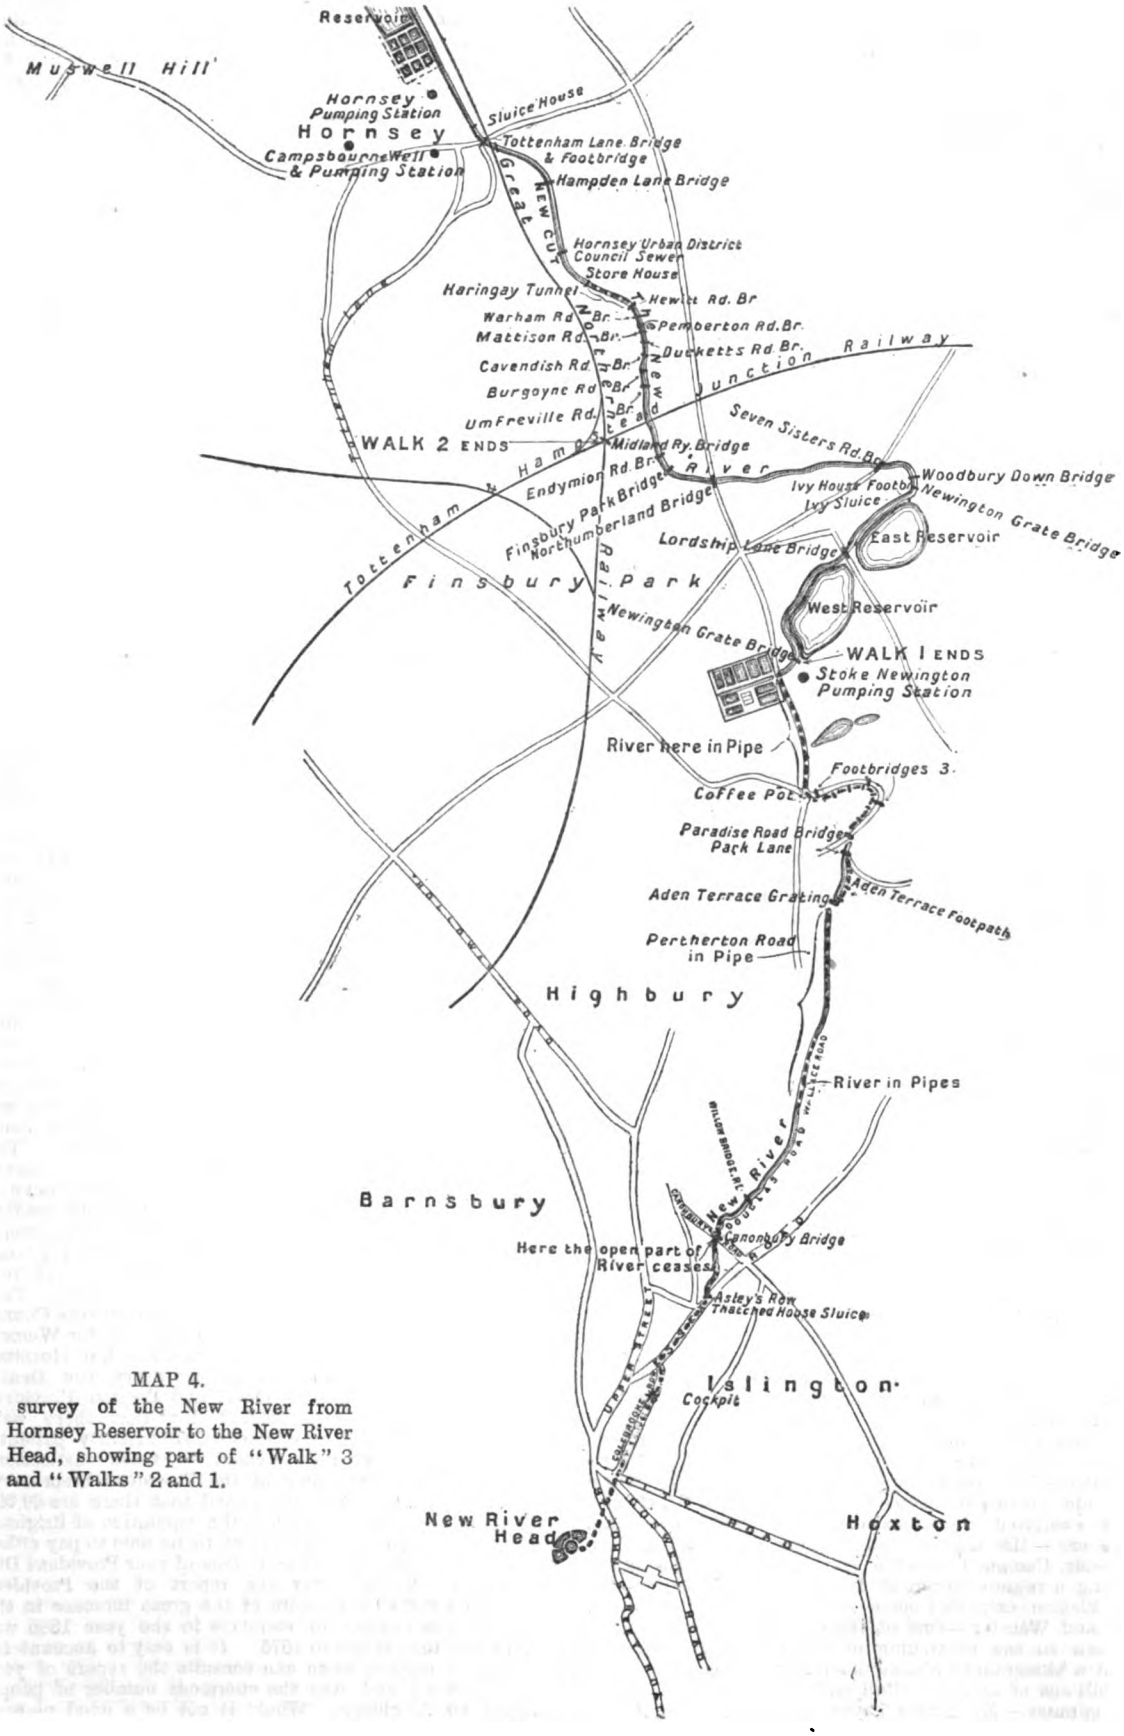
700 yards.—Here is a sluice house, to which the workmen of the New River Company have given the name of the Coffee Pot. It is so called because the water comes out of the pipe through a bell-mouthed opening. Here is the junction of walks 1 and 2. At this point the river again continues its course, passing into Clissold Park under a foot-bridge. This part of the river is protected on both sides by an iron spiked railing which has been put up and is kept in repair by the London County Council. There is a public footpath next to the upper bank.

350 yards.—Foot-bridge.

250 yards.—Foot-bridge.

300 yards.—Paradise-road. The river passes under this road and then through a garden.

60 yards.—Park-lane bridge. From this point there is a public footpath on the lower bank separated from the river by a high, spiked railing. On the upper side gardens go down to the river. The path passes by Aden Terrace.



350 yards.—Here there is a grating. This grating is of a new type. It is made entirely of iron, the meshes are ½ in. in width, and the pieces of iron which form the grating are also ½ in. in width and about 2 in. from before backwards. The pieces of iron which form the grating are fixed on to an iron rod, and all the meshes are of exactly the same size. Here the open part of the river ceases for a time. The water is conducted in a 48-in. iron pipe, which passes for a distance of about half a mile under Petherton-road, thirty yards along Grosvenor-road, and over the North London Railway at Canonbury Station and then along Wallace-road, at which point the pipe discharges itself again into an open channel. Wallace-road is on the upper bank for a distance of 600 yards, and then the river is crossed by Willow Bridge-road, Canonbury. Here Canonbury-grove is at the lower bank. At this point is a house which was once the ice house of Canonbury House, a place not without historic interest.

300 yards.—Canonbury bridge. The part of the river next Wallace-road is protected from trespassers by a 6 ft. cast-iron fence which extends along Paul's-road, Douglas-road, and Canonbury-road. At Canonbury bridge the river passes into a 54-in. pipe, which is at this point 2 ft. below the surface of the ground. The pipe passes along Astey's-row. Here there is a space covered with grass between an iron fence and the lower side and a wooden fence on the upper side. The width of this space varies from 40 ft. to 100 ft. It is the property of the Company, and is kept more or less private by the policemen on the beat.

At the end of this open space is the "Thatched House sluice." The house is now tiled and there is no sluice. The cottage is occupied by a caretaker and there is a small garden and a cockpit. From this point the pipe passes along the middle of the Essex-road. At a distance of about a quarter of a mile the pipe leaves the Essex-road, and is conducted down Colebrooke-row in a channel 6 ft. in height and 4 ft. in breadth for a distance of 30 yards, and here there is a cockpit, from which water is conveyed in a 36-in. pipe for a distance of 100 yards, then in a pipe 48 in. in diameter for the rest of the distance to the round pond at the New River Company's works at Islington. The course of the main is along Colebrooke-row, then between Colebrooke-row and Duncan Terrace, across the City-road and Goswell-road. After passing this road there is another manhole, which is situated in the playground belonging to Dame Owen's School, close to the iron fence. The pipe then passes under a garden at the corner of St. John-street, Clerkenwell, down Rosebery Avenue to New River Head, Clerkenwell.

(To be continued.)

THE ROENTGEN SOCIETY.

A HIGHLY successful inaugural meeting of the above recently-formed society was held at St. Martin's Town-hall, London, on Nov. 5th. Professor SILVANUS THOMPSON delivered the presidential address to a crowded audience. After a review of the antecedents and the circumstances under which Roentgen made his famous discovery in November, 1895, he announced that the learned professor had accepted the honorary membership of the new society. With the exception of anæsthetics and Lister's antiseptic system no discovery in the present century had done so much for operative surgery as that of the Roentgen rays. The first great application had been to the diagnosis of dislocations and fractures, the study of bone disease, and the detection of foreign bodies in various parts of the human frame. Dr. McKenzie Davidson had devised an ingenious apparatus by means of which a foreign body could be localised to within one-hundredth of an inch, the complicated geometry of oblique projection being simplified to the use of a callipers and a divided scale. The physiological effects had suggested that the rays might by nerve stimulation be made useful in some cases of blindness. Under some circumstances the normal retina possessed a faint perception for the rays. The matter had been fully discussed by their secretary, Dr. Walsh, in a book on the medical aspects of the rays. As regarded the physical problems presented by the rays there was a large field of problems awaiting solution. The rays had been found to possess a dissociating or, more strictly, an ionising effect on the molecules of gases through which they passed, with the result that electrified bodies in an atmosphere thus affected became discharged. Many theories had been advanced as to the exact nature of the rays; Crookes, Tesla, and others held them to consist of flights of atoms or sub-atoms; others that they were made up of transverse waves of excessively minute wave-length; others, again, regarded them as longitudinal; while Sir George Stokes thought they might be transverse waves, not in regular trains, but consisting of innumerable solitary waves. Another wide field of research lay in the investigation of analogous kinds of rays that affected photographic plates, such as those of the salts of uranium, fire-flies, glow-worms, and sticks of phosphorus. It was clear that their little society had an abundant field. Already three special journals existed—namely, in England, in America, and in Germany. In conclusion he appealed for the foundation of a London institution where earnest investigators might pursue the study of the physical sciences.

At the close of the address a vote of thanks was moved by Sir WILLIAM CROOKES and seconded by Professor GLADSTONE.

The rest of the evening was devoted to lantern demonstrations (Mr. Greenhill), screens (Mr. T. Moore), and an exhibition of apparatus and photographs.—The President showed Tesla's new coil, in which the primary was wound round the secondary and gave high frequency oscillatory discharges direct from any ordinary supply with little expenditure of energy.—Professor Gladstone showed photographs of metals in order of absorption of the rays, by which he proved that the process was governed by weight rather than by density.—Dr. Davidson and Mr. Hall Edwards each demonstrated a localising apparatus.—A good collection of coils and tubes was shown by Messrs. Newton, Cossor, Schall, Binko, Miller and Woods, and others.—Among the photographs were skiagrams of bullets taken by Mr. F. C. Abbott in the Turco-Greek War.—An interesting number of natural history specimens and Dr. Macintyre's cinematographic apparatus adapted to the rays were shown by Dr. Norris Wolfenden.—Dr. Walsh showed an interesting comparison of anæmic and turgid hands on the same plate.—Mr. Griffith Wilkin exhibited skiagrams of the temporal bone and middle ear.—Mr. Gifford brought some early and modern work.—Mr. Campbell Swinton sent an admirable collection, including a representation of Lord Salisbury's hand.—Dr. Barry Blacker exhibited some good work, as did Messrs. Moore and Webster.—One of the chief practical advances has been in the shortening of exposures.—Mr. Webster showed a skiagram of a hand taken in one second, and Mr. Greenhill one of an adult skull and of a pelvis each taken in five minutes.—Mr. Ernest Payne contributed photographs of mercurial contact breaks, and a number of interesting photographs were sent by Dr. Cotton (Bristol), Dr. Low, Dr. Newman, Dr. Nathan Raw (Liverpool), Dr. Coke Squance (Newcastle), Mr. Gerard Smith, Mr. Hinton Bateman, and others.—This branch of the exhibition was managed by Mr. Snowden Ward, while Mr. Webster organised a musical entertainment.

THE HOSPITAL REFORM ASSOCIATION.

A MEETING of this association was held at the Athenæum Hall, North-street, Brighton, on Friday last, Nov. 5th, under the presidency of Sir JOSEPH EWART.

Sir JOSEPH EWART made a spirited introductory speech. He referred to the statement of Sir William Broadbent to the effect that the present system was practically the misappropriation of charitable money, and that a good deal of that money if saved could be better utilised in further perfecting the arrangements for the treatment of those who were really deserving and really required relief.

Mr. GARRETT HORDER, the honorary secretary of the association, then gave a short address, in which he said: "The question we have met to discuss this evening is one that may fairly be said to affect all classes of society, and it would be a great mistake to discuss it from a professional point of view only. The aim of the Hospital Reform Association has been to convince the public that the present system of administering medical relief in our hospitals and dispensaries is neither fair to the philanthropists who support them, to the deserving sick poor who seek relief in them, nor to the medical profession, without whose aid they could not be carried on. I have mentioned these points because it has been stated from time to time that the association with which I am connected was established for the sole purpose of looking after the interests of the medical profession. That this is not the case is, I think, proved by the fact that we have invited laymen to become members, and have invariably at all our meetings sent invitations not only to the managers of hospitals, but to all persons taking an interest in the organisation of charities. That reforms are wanted will hardly be denied, but if there are any who are sceptical about it I would refer them to the pages of THE LANCET and the *British Medical Journal*, to the proceedings of the Charity Organisation Society, and locally to one of your esteemed practitioners, Dr. Francis Waring. To Dr. Waring must be given the credit for pointing out the necessity that exists for reform in the administration of the Brighton medical charities. Hospital abuse may be divided into two distinct parts, one part—and, in the opinion of many, the most important part—being the attendance of people who do not stand in need of hospital treatment; and the other being the attendance of persons who could afford to pay for the treatment of their complaints. This form of abuse is not confined to the working-classes. Evidence has been forthcoming proving that tradesmen of all classes have sought and obtained relief in our medical charities. Subscribers themselves often abuse their privileges by recommending members of their own household for treatment. Reform is also required in other directions. There is nowadays an undue multiplication of hospitals. Take your own town, for instance. You have the Sussex County Hospital, the Sussex Eye Hospital, the Hospital for Women, the Hospital for Sick Children, the Throat and Ear Hospital, the Brighton, Hove, and Preston Dispensary, the Dental Hospital, and the Brighton, Hove, and Preston Provident Dispensary. In the year 1895 I find that there were 2392 in-patients, 35,522 out-patients, 3476 casualty patients, and 1172 maternity cases treated at these institutions exclusive of the cases treated at the Provident Dispensary. It will, however, hardly be contended that there are 40,000 persons—or more than a fourth of the population of Brighton and Hove combined—so poor as not to be able to pay either private practitioners or the small fees of your Provident Dispensary. On looking over the report of the Provident Dispensary I find that in spite of the great increase in the population the number of members in the year 1895 was actually less than it was in 1876. It is easy to account for this want of support when one consults the report of your Free Dispensary and sees the enormous number of people attended by its officers. Would it not be a good plan to

Digitized by Google

amalgamate the two institutions and thus encourage the growth of thrifty habits?"

Dr. FRANCIS WARING then moved:—

"That this meeting is of opinion that the time has arrived when an investigation should be held into the mode of administering medical relief in the hospitals and dispensaries of Brighton and Hove, and it is further of opinion that this investigation should be conducted by a committee which should be representative of all interests concerned."

In moving the resolution he disclaimed all unfriendly spirit to the institutions of the town, but he believed that some step should be taken to safeguard their charities against abuse.

Mr. S. COWELL who supported the resolution, claimed that the abuse at the Sussex County Hospital was next to *nil*.

Mr. R. P. HOOPER, Dr. DILL, Mr. DENNANT, Mr. DODD, and the Rev. C. W. BOND also spoke in favour of the resolution, which was carried amid applause.

Mr. Hooper, Dr. Waring, Mr. Dodd, and Dr. Marsh were appointed a provisional committee.

The meeting closed with a vote of thanks to the chair.

INTERNATIONAL LEPROSY CONFERENCE, BERLIN, 1897.

THE following is a condensed report of the conclusions of the Conference:—

"At the close of the debates of the International Leprosy Conference, Berlin, 1897, the secretaries have the honour to present the following short report of the general conclusions of the Conference. They believe that such a *résumé* will be especially desirable for those members who have been delegated by their respective Governments and who have to make reports on the results of the Conference.

"As might be expected, a considerable portion of the discussion has related to the bacillus lepræ, which the Conference accepts as the virus of leprosy, and which for upwards of twenty-five years has been known to the scientific world through the important discovery of Hansen and the able investigations of Neisser.

"The conditions under which the bacillus grows and develops are still unknown, as well as the way of its invasion into the human system; but from the discussions of the conference it seems probable that an unanimity of opinion will soon prevail in reference to its modes of subsequent dissemination within the human body. Very interesting observations have been brought forward in connexion with the elimination of the bacilli in large quantities by means of the skin and nasal and buccal mucous membranes of lepers; it is desired that such observations be confirmed where opportunities occur. The question is of very great importance to those who are entrusted with the care of the public health, as leprosy is now acknowledged to be a contagious disease.

"Every leper is a danger to his surroundings, the danger varying with the nature and extent of his relations therewith and also with the sanitary conditions under which he lives. Although among the lower classes every leper is especially dangerous to his family and fellow workers, cases of leprosy frequently appear in the higher social circles. The theory of heredity of leprosy is now further shown to have lost ground in comparison with the at present generally accepted theory of its contagiousness. The treatment of leprosy has only had palliative results up to the present time. Serum therapy has so far been unsuccessful.

"In view of the virtual incurability of leprosy and the serious and detrimental effects which its existence in a community causes, and considering the good results which have followed the adoption of legal measures of isolation in Norway, the Leprosy Conference, as a logical issue of the theory that the disease is contagious, has adopted the following resolution proposed by Dr. Hansen and amended by Dr. Besnier: '1. In such countries where leprosy forms foci or has a great extension we have in isolation the best means of preventing the spread of the disease. 2. The system of obligatory notification, of observation and isolation as carried out in Norway, is recommended to all nations with local self-government and a sufficient number of physicians. 3. It should be left to the legal authorities after consultation with the medical authorities to take such measures as are applicable to the special social conditions of the districts.'

"Secretaries of the Conference:
PHIN. S. ABRAHAM, London.
ED. ARNING, Hamburg.
A. VON BERGMANN, Riga.
E. DUBOIS HAVENITH, Bruxelles.
J. J KINYOUN, Washington.
G. THIBIERGE, Paris.
EDV. EHLERS, Copenhagen (Gen. Secretary)."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Dumbartonshire County District.—The general death-rate of the landward portion of this county (14·91) for 1896 was the lowest on record, and fewer cases of infectious disease were notified than in any year since notification came into force. There were no outbreaks of note during the year, but one case of typhus fever was notified. Dr. McVail reports that a site for two isolation hospitals has now been decided upon, one for the western district of the county and the other for two parishes in the eastern district. In the former district a good scheme has been arranged, after apparently considerable difficulty, with the burgh of Dumbarton. Some progress has been made in the matter of river pollution, but, as Dr. McVail observes, the amount is not commensurate with the energy expended upon the subject. Attempts are, it appears, being made to prevent vessels anchoring in, or plying on, the Garelock from discharging excrement or refuse into the water. As regards water-supply Dr. McVail reports that the proposed supply for two villages had to be given up owing to the peaty nature of the water. It was proposed by certain analysts to treat the water by placing blocks of sulphate of alumina in its course and allowing the peaty matter to precipitate in the reservoir. Dr. McVail, however, after due consideration, did not feel himself justified in recommending this supply.

Stirling County District.—Stirlingshire, like unto Dumbartonshire Dr. McVail's other county, had for 1896 a death-rate lower than any yet recorded—i.e., one of 13·94 per 1000 as compared with a rate of 16·0 for the whole of Scotland; the lowest experienced since the operations of the Registration Act commenced in 1855 Complaints of the poisoning of fish in the River Boney gave rise to some interesting revelations. It seems that in a certain pool in the river, which was a suitable spot for fishing, there has been deposited a considerable quantity of lime. This lime has, it appears, been placed in the pool in order to sicken the fish and render their capture more easy. Caustic soda is, Dr. McVail says, sometimes used for the same purpose, its solubility rendering its detection more difficult than is the case with lime. It is clear, as Dr. McVail remarks, that where such practices as these obtain the prevention of pollution from other sources will be of but little avail in the matter of the protection of fish. The eastern district of Stirlingshire has been provided with good hospital accommodation, and the western district is in a fair way to be similarly equipped.

Lanark County District.—Four new isolation hospitals were occupied in this county during 1896, and in the present year two others will be completed. The Rivers Pollution Acts are being vigorously administered throughout the county by the public health committee of the county council. The worst offenders, however, appear to be the burghs, and the committee of the special drainage district have decided to take the matter in hand resolutely. Apart from the question of pollution by sewage it appears that there are between fifty and sixty collieries carrying on the process of coal dross washing, a process which is apt to cause very great inconvenience to manufacturers. Dr. J. T. Wilson has made a very interesting report upon this subject of coal washing, and it seems that the effluent from the coal washing process contains suspended solids to the extent of from 1 grain per gallon to as much as 29,985 grains. Seven collieries were reported to the Secretary for Scotland with a view to obtaining power for prosecution, but it appears from the

Digitized by Google

special attention which has been devoted to these cases much improvement has in the meantime resulted. Dr. Wilson has submitted to the executive committee of the county council an instructive report upon tuberculosis in the county of Lanark, and he has communicated with the county veterinary inspectors in reference to the extent of bovine tuberculosis. One officer reports that as a result of superintending the disposal of some 3000 carcasses, chiefly of dairy stock, he found that fully 25 per cent. were tuberculous. Another reports that, in his opinion, the disease exists to the extent of about 20 per cent. A third inspector reports that in some of the large dairies one-third to a half, and at times the whole of the herd, are affected. The experience of Mr. John Spier, of Newton Farm, Cambuslang, is extremely interesting. He supplies milk from such cows only as have stood the tuberculin test. During the past two years he has tested some 200 cows for his own use, the cows ranging from three to seven years of age; and although he purchases the very best class of cows he finds fully 30 per cent. react to the tuberculin test. Mr. Spier has tested stock for other persons, and he has found a few stocks almost free, while a good many have almost the whole number affected. Dr. Wilson gives an interesting account of the methods of testing and the process of exclusion practised in Paris, and of Professor Bang's experience with a Danish herd. From an account by Mr. James Wilson of the Castlecraig herd of the Aberdeen Angus cattle, it seems that "the spread of the disease has been completely arrested," the only alteration in the management of the herd being the annual testing and the separation of the unsound from the sound. As Dr. Wilson observes, these tests are most encouraging provided tuberculin can be absolutely relied upon as a test.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6829 births and 3822 deaths were registered during the week ending Nov. 6th. The annual rate of mortality in these towns, which had been 16·9 and 17·6 per 1000 in the two preceding weeks, further rose last week to 18·1. In London the rate was 18·5 per 1000, while it averaged 17·9 in the thirty-two provincial towns. The lowest rates in these towns were 11·2 in Croydon, 11·5 in Leicester, 12·1 in Derby, and 13·9 in Bristol; the highest rates were 21·5 in Wolverhampton, 21·8 in Oldham, 22·1 in Burnley, and 23·4 in Liverpool. The 3822 deaths included 412 which were referred to the principal zymotic diseases, against 429 and 463 in the two preceding weeks; of these, 128 resulted from measles, 82 from diphtheria, 64 from diarrhœa, 51 from "fever" (principally enteric), 46 from scarlet fever, and 41 from whooping-cough. The lowest death-rates from these diseases were recorded in Birkenhead, Salford, Croydon, Brighton and Nottingham, and the highest rates in Preston, Halifax, Burnley, and Wolverhampton. The greatest mortality from measles occurred in Gateshead, Manchester, Blackburn, Halifax, and Wolverhampton; from "fever" in Huddersfield and Gateshead; and from diarrhœa in Oldham, Blackburn, and Preston. The mortality from scarlet fever and from whooping-cough showed no marked excess in any of the large towns. The 82 deaths from diphtheria included 59 in London, 5 in Cardiff, 3 in Wolverhampton, and 3 in Birmingham. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals on Saturday last, the 6th inst. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on the same date was 3680, against 3725, 3685, and 3682 at the end of the three preceding weeks; 339 new cases were admitted during the week, against 440, 342, and 416 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 279 and 326 in the two preceding weeks, further rose to 363 last week, but were 37 below the corrected average. The causes of 42, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Oldham, Bradford, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Liverpool, Blackburn, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 19·9 per 1000 in the two preceding weeks, further declined to 18·8 during the week ending Nov. 6th, but exceeded by 0·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·4 in Leith and 11·9 in Perth to 21·7 in Paisley and 26·2 in Greenock. The 560 deaths in these towns included 18 which were referred to scarlet fever, 16 to whooping-cough, 14 to diarrhœa, 12 to measles, 5 to "fever," and 5 to diphtheria. In all, 70 deaths resulted from these principal zymotic diseases, against 86 and 79 in the two preceding weeks. These 70 deaths were equal to an annual rate of 2·3 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of scarlet fever, which had been 4 and 12 in the two preceding weeks, further rose to 18 last week, of which 10 occurred in Edinburgh and 5 in Glasgow. The 16 deaths referred to whooping-cough exceeded by 1 the number in the preceding week, and included 12 in Glasgow and 3 in Aberdeen. The fatal cases of measles, which had increased from 3 to 8 in the four preceding weeks, further rose to 12 last week, of which 6 occurred in Glasgow and 6 in Greenock. The 5 deaths referred to different forms of "fever," showed a slight further decline from those registered in recent weeks, and included 3 in Glasgow, where 4 of the 5 fatal cases of diphtheria were also recorded. The deaths from diseases of the respiratory organs in these towns, which had been 144 and 137 in the two preceding weeks, rose again to 142 last week, and were 12 above the number in the corresponding period of last year. The causes of 27, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·2 and 28·2 per 1000 in the two preceding weeks, declined again to 21·5 during the week ending Nov. 7th. During the past five weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 16·9 in London and 18·6 in Edinburgh. The 144 deaths registered in Dublin during the week under notice showed a decline of 45 from the number in the preceding week, and included 12 which were referred to the principal zymotic diseases, against numbers declining from 39 to 8 in the six preceding weeks; of these, 8 resulted from "fever," 2 from diphtheria, 1 from whooping-cough, and 1 from diarrhœa. These 12 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rate during the same period being 2·5 both in London and in Edinburgh. The deaths referred to different forms of "fever," which had been 7, 6, and 0 in the three preceding weeks, rose again to 8 last week. The fatal cases of diphtheria, which had been 1 in each of the two preceding weeks, rose to 2 last week. The mortality from diarrhœa was below that recorded in any recent week. The 144 deaths in Dublin last week included 21 of infants under one year of age and 30 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers recorded in the preceding week. Five inquest cases and 3 deaths from violence were registered; and 51, or more than a third, of the deaths occurred in public institutions. The causes of 5, or more than 3 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING OCTOBER, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during October in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 16·0 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 11·2, 10·2, and 13·3 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Paddington, Hammersmith, Chelsea, St. George Hanover-square, Westminster, Holborn, and Lewisham; while they showed the largest excess in Clerkenwell, Limehouse, Poplar, St. Olave Southwark, Rotherhithe, Battersea, and

Plumstead. One case of small-pox was notified in London during October, corresponding with the number in each of the two preceding months; this case belonged to Bethnal Green sanitary area. No small-pox case was admitted into any of the Metropolitan Asylum Hospitals during October, and no patients remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a further marked increase upon that recorded in recent months; this disease was proportionally most prevalent in Fulham, Hackney, St. Giles, St. Luke, Limehouse, St. Olave Southwark, Rotherhithe, Battersea, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 3571 scarlet fever patients at the end of October, against 3064, 3390, and 3585 at the end of the three preceding months; the weekly admissions averaged 387, against 364, 346, and 350 in the three preceding months. The prevalence of diphtheria in London showed a considerable further increase upon that recorded in the two preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in Clerkenwell, St. Luke, Bethnal Green, St. George-in-the-East, Limehouse, St. Saviour Southwark, Battersea and Lee. There were 1029 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of October, against 957, 1006 and 1033 at the end of the three preceding months; the weekly admissions averaged 155 against 139, 131, and 150 in the three preceding months. The prevalence of enteric fever in London during the month under notice showed a marked further increase upon that recorded in recent months; this disease was proportionately most prevalent in St. Pancras, Stoke Newington, Strand, City of London, St. George-in-the-East, and Limehouse sanitary areas. The Metropolitan Asylum Hospitals contained 175 enteric fever patients at the end of October, against 82, 133, and 173 at the end of the three preceding months; the weekly admissions averaged 26 against 20, 26, and 28 in the three preceding months. Erysipelas showed the highest proportional prevalence in St. Pancras, St. Giles, St. Martin-in-the-Fields, Bethnal Green, St. George Southwark, and Rotherhithe sanitary areas. The 27 cases of puerperal fever notified in London during October included 4 in Newington, 4 in Lambeth, and 2 each in Fulham, Chelsea, Marylebone, St. Pancras, Poplar, and Plumstead sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, October 30th, the deaths of 5518 persons belonging to London were registered, equal to an annual rate of 16·1 per 1000, against 18 3, 23 7, and 15·6 in the three preceding months. The lowest death-rates during October in the various sanitary areas were 9 4 in Hampstead, 9 5 in Stoke Newington, 10 3 in St. Martin-in-the-Fields, 10·6 in Lee, 11 3 in Lewisham and in Plumstead, and 11 5 in Wandsworth; the highest rates were 22·7 in Limehouse, 23 1 in St. George-in-the-East, 23 3 in Clerkenwell, 23 8 in Strand, 24 7 in Whitechapel, 26 1 in St. Olave Southwark, and 28·2 in Holborn. During the four weeks of October 723 deaths were referred to the principal zymotic diseases in London; of these, 216 resulted from diphtheria, 166 from measles, 100 from diarrhœa, 84 from whooping-cough, 79 from enteric fever, 76 from scarlet fever, 1 from typhus, and 1 from an ill-defined form of continued fever. These 723 deaths were equal to an annual rate of 2·1 per 1000; in the various sanitary areas the lowest zymotic death-rates were recorded in Paddington, Hammersmith, St. Giles, Strand, and Lewisham; and the highest rates in Westminster, St. James Westminster, Clerkenwell, St. Luke, St. George-in-the-East, Poplar, St. Saviour Southwark, and St. Olave Southwark. The 166 fatal cases of measles were 54 above the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Westminster, St. George-in-the-East, St. Saviour Southwark, St. George Southwark, Newington, Bermondsey, and Camberwell sanitary areas. The 76 deaths referred to scarlet fever were 34 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in St. James Westminster, Limehouse, Bermondsey, and Greenwich. The 216 fatal cases of diphtheria were 22 above the corrected average number; the mortality from this disease was highest in Clerkenwell, Shoreditch, Bethnal Green, Limehouse, Poplar, St. Saviour Southwark, Woolwich, and Plumstead sanitary areas. The 84 deaths from whooping-cough were 4 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Clerkenwell, St. Luke, Bethnal Green, and Limehouse. The fatal case of typhus was of a person belonging to Bethnal Green sanitary area. The 79 deaths referred to enteric fever were 9 above the corrected average number; this disease was proportionally most fatal in City of London, St George-in-the-East, Mile End Old Town, and Rotherhithe sanitary areas. The 100 fatal cases of diarrhœa were 76 below the corrected average number. In conclusion, it may be stated that the mortality in London from these principal zymotic diseases during October was nearly 4 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was equal to 132 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Stoke Newington, St. Luke, City of London, Lewisham, Lee, and Plumstead; and the highest rates in St. James Westminster, Clerkenwell, Bethnal Green, St. George Southwark, Newington, and Rotherhithe.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN C. A. YOUNG has been placed under orders to embark for India shortly. Surgeon-Majors Coutts, Lilly, and Johnson, and Surgeon-Captains Pearse, Dalton, Tyrrell, and Mansfield have arrived home from India in the transport *Nubia*.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Colonel D. E. Hughes, M.D., having applied to retire on pension, Surgeon-Colonel G. Bainbridge, M.D., has been appointed Surgeon-General with the Government of Bombay, vice Surgeon-Major-General H. Cook, M.D., deceased.

NAVAL MEDICAL SERVICE.

Fleet-Surgeon James Thomas William Stenteford Kellard has been placed on the retired list of his rank.

The following appointments have been announced:—Staff-Surgeons: John Ottley to the *Venus*, and William H. Norman to the *Rupert*, additional, for Gibraltar Hospital. Surgeon A. E. Merewether to the *Venus*.

VOLUNTEER CORPS.

Artillery: 1st Norfolk (Eastern Division, Royal Artillery): Surgeon-Lieutenant-Colonel T. H. Moxon resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. 4th Lancashire: Surgeon-Major T. F. Young, M.D., to be Surgeon-Lieutenant-Colonel. *Rifle:* 4th Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Captain T. Lyndon, M.D., resigns his commission. 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant E. P. A. Mariette, M.B., to be Surgeon-Captain. 2nd Volunteer Battalion the York and Lancaster Regiment: Brigade-Surgeon-Lieutenant-Colonel J. Blackburne resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement, vacating at the same time his appointment as Senior Medical Officer to the East Yorkshire Volunteer Infantry Brigade.

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the under-mentioned officers of the Volunteer Force:—*North-Eastern District: Artillery:* 2nd East Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Lieutenant-Colonel John Sherburn, M.B. *Western District: Rifle:* 4th Volunteer Battalion the Devonshire Regiment: Brigade-Surgeon-Lieutenant-Colonel John Raglan Thomas, M.D.

THE CONVEYANCE OF INVALIDS BY SEA.

Surgeon-in-Chief Bonnafy is the author of the leading paper in the *Archives de Médecine Navale et Coloniale* for

Digitized by Google

October, his theme being the comparative merits as invalid carriers of Government transports and chartered steamers. When Cochin China was first occupied by the French invalids used to be conveyed home in ordinary transports, but the unsuitability of this class of vessel for such a purpose soon came to be acknowledged, thanks mainly to the representations of Dr. Lalluyeaux d'Ormay, who was the principal medical officer of the colony. Admiral La Grandière, the governor, having adopted his adviser's views, an engineer named Cazelles was deputed to make a study of our late Anglo-Indian troopships, and the result was a fleet of seven specially designed hospital transports at a cost of about a million and a quarter sterling, the first only, *l'Annamite*, being constructed of wood and the others of iron. These vessels commenced to run in 1878, and continued to be more or less actively employed until the end of 1895, when they were immobilised. In 1885, however, it was found necessary to hire supplementary transports from private sources, and, curiously enough, during the next ten years, from 1886 to 1895 inclusive, the number of invalids carried in each class was almost identical, the totals having been 11 322 and 11,343 respectively. During these voyages 214 deaths took place in the Government vessels and 302 in those that had been chartered, and it is upon these figures that Dr. Bonnafy relies to prove the superiority of the hospital transports. He has no fault to find with the way in which the invalids were treated on board the private steamers. The utmost goodwill was invariably manifested by captains and *personnel*; but even apart from statistics he thinks it stands to reason that a specially constructed vessel under military discipline is bound to yield the best results.

Literature for Army Hospitals.

The Government of India has issued an appeal for gifts of literature for the use of sick and wounded soldiers in military hospitals attached to the forces operating upon the Indian frontier. Light packets of books, periodicals, and newspapers will be conveyed free of charge for the use of hospitals by the Post Office in India. Packets should be addressed to "the Principal Medical Officer, Tochi Field Force," "Malakand Field Force," or "Tirah Expeditionary Force," as the case may be, and should be very clearly superscribed, "For sick soldiers." Why should not the proprietors of some of the illustrated papers published in London and large library book firms, like Mudie and W. H. Smith and Sons, put themselves in communication with the India Office in this country and offer some of their old, spare, and surplus papers and copies of light literature for the use of the sick and wounded in hospital provided that the Government would undertake to forward them?

Deaths in the Services.

Staff-Surgeon John Noble, R N. (retired), at York, on the 8th inst. He was born in 1832, and entered the navy shortly after the commencement of the Russian War, in 1855, being appointed to serve in the ship *Majestic*, under Captain James Hope, ordered to the Baltic with the fleet under the command of Admiral Dundas. During a period of nearly twenty years he served on various ships in every quarter of the globe, being in the Chinese War of 1857, the Mexican Expedition of 1861, and in the Abyssinian Expedition of 1868. During the Chinese War he suffered so severely from fever that his life was despaired of, and he felt the effects as long as he lived. (Baltic medal for the Russian Campaign of 1854-55, the Canton medal and clasp for the Chinese War of 1857, and the Abyssinian medal for the campaign under Napier in 1868.)

Volunteer Medical Association.

The Council of the above association are now prepared to provide the instruction necessary for passing the examination for the proficiency certificate. The course will be confined to members of the Association, and will be free, a small charge being made to cover necessary expenses only. Instruction will be carried out either by correspondence, or, in the case of those who are resident in London or sufficiently near it, by lectures. The instructors are selected by the Council from among their members. Officers desiring to avail themselves of this course are asked to give notice to Surgeon-Major Watson, Hay Tor, Dennington-park, N.W. It is intended to commence the first course on Nov. 23rd.

The Gallant Conduct of Surgeon-Captain W. G. Beyts.

Surgeon-Captain W. G. Beyts has been specially brought to the notice of the military authorities in India for his gallant conduct in saving the life of Lieutenant North. We refer in more detail to the matter in another column.

Lieutenant E. W. Costello, V.C., on whom Her Majesty recently conferred the Victoria Cross for valour in connexion with the present Indian Frontier Campaign is a son of Surgeon-Colonel C. P. Costello, Indian Medical Service (retired), himself an officer of very distinguished service in the field.

Her Majesty the Queen has granted the Jubilee Medal to Surgeon-Major-General J. B. Hamilton, Principal Medical Officer of the Western District.

Correspondence.

"Audi alteram partem."

"THE MECHANISM OF DEATH FROM CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—I would ask for space in your journal to offer criticism on Mr. Alexander Wilson's article on the above subject, published in THE LANCET of Sept. 11th, 1897, p. 656. In publicly describing cases of this sort, on which a theory as to the cause of death from chloroform poisoning is built up, it is essential that the observation should be of the most accurate and the report of the fullest description, and that for two reasons — first, that the reader may determine how far he may trust the accuracy of the observer, and, secondly, that he may determine for himself the cause of death—that he may determine, that is, whether death was the result of chloroform poisoning or not, and if it were, in what manner it occurred. It cannot be too strongly urged that in building up from the symptoms of certain cases a theory as to the mechanism of death from chloroform it is of absolute importance to prove that these symptoms were caused by the drug. No one will deny that death under chloroform may result, and does result, from causes quite apart from poisoning, such as, to give a single instance, from mechanical obstruction of the air passages. Anyone who wishes to build up a theory as to the mechanism of death from chloroform poisoning, must first take the trouble to show that the deaths on the symptoms of which he depends for the facts on which his theory is built are the result of chloroform poisoning.

In considering the cases given by Mr. Wilson let us first take Case 3 and see how far it fulfils these essentials. The report of it could scarcely give less information. Let it be noted that a failure of circulation so great that when the skin was incised no blood flowed passed entirely unnoticed. The administrator's observation cannot, then, be relied upon as correct, for it was manifestly imperfect. There is no evidence that he ascertained that the free respiration going on was accompanied by any entry of air into the chest. Indeed, no attempt is made to show that the death was the result of chloroform poisoning it is simply taken for granted. Of Case 2 the same may be said. The description is entirely inadequate. "Some peculiarity" was noticed about the colour of the face, and that by the operator and not by the anæsthetist. It may have been the pallor of shock or the duskiness of suffocation; we are not told. Nor do we know whether air was entering the chest or not. Blood or a portion of an adenoid growth in the air passage would be clinically shown by deep respiratory movements and a "peculiarity" in the colour of the face. As to failure of circulation its state is not even mentioned. In reading Case 1 the first thing which strikes one is that the whole series of dangerous events followed the beginning of the operation. They are symptoms such as are found associated, quite apart from chloroform, with painful shock; and they are those which occur from the powerful stimulus of a cut when the patient is not fully under the influence of the anæsthetic. In a word they are the symptoms not of danger from chloroform poisoning, but of shock from the operation due to insufficiency of chloroform. Nothing can be clearer from the description than that the shock immediately followed and presumably resulted from the intense stimulus of thrusting a gouge in the antrum. Then why lay it at the door of the chloroform? In Case 6, given as an illustration of a previously stated theory that failure of the circulation taking place at an early stage in the

Digitized by Google

administration of chloroform leads to convulsions, there is not the slightest evidence offered of any failure of circulation occurring previously to the convulsions. That cerebral anæmia will cause convulsions is one matter, but to say that because there were convulsions in this case, therefore there was antecedent failure of circulation is begging the question. We are told that the man "appeared as if about to vomit" but we are not told whether or not a post-mortem examination was made and vomited matter found in the trachea; nor are we even told whether or not he was the subject of epileptic fits. Indeed, no attempt is made to prove that there was either failure of circulation previously to the convulsions or, indeed, that the death was due to chloroform poisoning. In Case 7 there is the same want of detail and apparent lack of observation. The description is so worded that it reads as if it was only on the operator's wishing to begin his work that the patient's critical condition was noticed. Such a description is one to be avoided if one wishes to build up a theory on it. Still, the clinical picture is familiar enough. It is that of a man whose air passage is obstructed, say, by the root of his tongue. His respiratory movements are marked, his face becomes congested, but his pulse rapidly fails, and then his respirations do the same, and finally cease. I do not say that this is what occurred in this case; but it is absurd to ignore the fact that the symptoms are capable of being explained without the question of chloroform poisoning being considered, that no attempt is made to show that this is not the case, and that according to that explanation the failure of circulation is secondary.

On studying these cases one is driven to the following conclusions: That in none of these cases is the report sufficiently full to make it of value; that in none is an attempt made to show that the deaths occurred from chloroform poisoning; that in none is it proved that there was primary failure of circulation (indeed in Case 2 the state of the circulation is never referred to!); and that all can be explained readily as due to some well recognised cause apart from chloroform poisoning. This is not the foundation on which to build up a theory as to the cause of death from this drug. The chloroform controversy can only be settled by careful and minute clinical observation and record, made by men who are determined to ascertain in the case of every death under chloroform in which they are the administrators whether death resulted from chloroform poisoning or not. When the administrator has made this decision he will then, and not till then, be able to give his opinion as to the way in which the poison killed, but let me repeat, his first duty is to prove that the cases he is describing are cases of chloroform poisoning, and that Mr. Alexander Wilson has entirely omitted to do.—I am, Sirs, yours truly,

CLAYTON A LANE, M.D. Lond.,
Surgeon-Lieutenant, I.M.S.

Camp Shinowrie, Oct. 15th, 1897.

THE HOSPITAL SATURDAY FUND AND THE DISTRIBUTION OF AWARDS.

To the Editors of THE LANCET.

SIRS,—Your leading article on the recent meeting of the Hospitals Association emboldens me to ask for a little space in your columns. I agree, as I said at that meeting, that effective criticism is required, but, of course, to be effective it must be based on knowledge of the facts. You seem to fall into the common mistake that the Hospital Saturday Fund system of distribution is somehow based on its supposed inordinate desire for letters of recommendation. This is an entire mistake. If a hospital answers in reply to our question whether it will allow letters in the same proportion as to other subscribers, that it will not, it looses one mark, which will affect the award to the extent of from £1 15*s.* to £2; for the rest the award proceeds according to rule, and the question of letters is not even considered. It is true that we find that our subscribers do make demands on us for letters of recommendation which cannot be satisfied out of the letters which they give us, as they give them to the Hospital Sunday Fund, in return for our grants. We therefore, before deciding what amount is to be distributed, deduct an amount sufficient to enable us to meet these demands and purchase the letters on the terms agreed on between ourselves and the hospital. But the matter is really a very small one. At our last distribution we paid away strictly according to our published system £16,059 10*s.* to different medical charities and reserved £950. Last year, when the amount reserved was £900 (the figures for this year are not, of course, yet complete), we spent £543 1*s.* in the purchase of hospital letters and £584 1*s.* 6*d.* in sending patients to convalescent homes, towards which the patients themselves paid £293 14*s.* 6*d.* Of course, with regard to letters sent in return for our grants we are in the same position as the Hospital Sunday Fund, which receives letters practically in the case of the in-patient hospitals in the same proportion as we do, and distributes them among the ministers of religion. I do not wish to defend the alleged demerits of the Hospital Saturday Fund in this respect, and will only ask your readers to remember that if we sin we sin in company with the Hospital Sunday Fund, and that any contribution we make to the funds of the hospitals is gathered in the main from those who would in any case find their way to the hospitals.

I should like, if I am not trespassing too much on your space, to add a few words on the discussion which took place, as I am in cordial agreement with you as to the advantage which would be obtained by further discussion. I am extremely grateful to our critics, and hope I have learnt a good deal which will be useful to us; but I was "unwilling to verge towards anything which might be considered to be personality." Your leading article has to some extent removed that unwillingness, so I venture to point out that apart from the letter question all the criticisms were aimed at that part of our system which deals with the awarding for economy and efficiency marks. Not a word was said by any speaker about our main principle of awarding marks for relief which corresponds very nearly to the "arithmetical basis" of the Hospital Sunday Fund. This "arithmetical basis," according to Sir Sydney Waterlow, is "raised or lowered at the discretion of the committee," but the meeting was left in complete ignorance as to the principles upon which the committee act in raising or lowering the basis beyond the statement that the data which we consider in the manner I described were considered by them also. That the power exercised by the committee is very great is obvious from the following example. The arithmetical basis of Guy's Hospital ascertained according to the method described cannot have been very different in 1896 and 1897, but I find that the award in 1896 was £814 11*s.* 8*d.* out of a total of £41,829, while in 1897 it was £1312 10*s* out of £39,705 15*s.* 6*d.*, an increase on a smaller total to be distributed of not less than 62 per cent., or, in other words, while in 1896 rather less than 2 per cent. of the total amount to be distributed was awarded to Guy's Hospital, in 1897 rather more than 3½ per cent. is given to that hospital. I have no doubt that this is in accordance with the principles adopted by the distribution committee, but some information as to the principles which permit so great a variation would be useful and instructive. Had I on behalf of the Hospital Saturday Fund maintained the same silence on this part of our system, apparently not even the energy of my friend Sir Henry Burdett could have galvanised the discussion into life.

I am, Sirs, your obedient servant,

R. B. ACLAND,
Chairman, Hospital Saturday Fund.

Hare-court, Temple, Nov. 8th, 1897.

"THE HOSPITALS, THE PROFESSION, AND THE PUBLIC."

To the Editors of THE LANCET.

SIRS,—I cannot think that the general practitioners will welcome with any heartiness Sir Henry Burdett's proposal for paying annexes to our hospitals. They would in my humble opinion pauperise the public, who would pay inadequate fees, and ruin the general practitioner; and while accomplishing their undesigned ends would not supply any better clinical treatment for the poorer sick of all grades than can now be obtained. If Sir Henry Burdett, having satisfied the exigencies of the examiners, becomes a medical man, and then aspires to occupy a seat on the General Medical Council as a Direct Representative, it is clear to me that he must alter his attitude towards the general practitioner or he will not obtain the necessary votes. He has possibly damaged the general practitioner already by his words, whatever interpretation he may wish to have set upon them. The *World* of Oct. 27th says with reference to his speech that "Sir Henry Burdett acutely implied that were the poorer medical men better educated their patients would not go to hospitals." So that

Digitized by Google

whatever Sir Henry Burdett's views may be he has contrived to cast a slur on the rank and file of the profession. For it cannot be good for us general practitioners that a journal of good repute and very large lay circulation should say such things of us, even on Sir Henry Burdett's authority.

I am, Sirs, yours faithfully,

Tillingham, Nov. 7th, 1897. F. S. D. HOGG.

A NOTE ON CYCLING.

To the Editors of THE LANCET.

SIRS,—One of the advantages of cycling is that it renders possible a great deal of outdoor exercise without fatigue. How are we to explain the wide difference in this respect between it and the natural modes of progression? There are, I suggest, two chief reasons. In cycling (1) the legs have not to support the body; and (2) the vascular column is shortened. 1. The legs having no work of support can devote themselves entirely to that of propulsion, whereas in walking and running much of the energy expended by the muscles of the lower extremities is spent in supporting and balancing the body. Even the mere act of standing involves a considerable expenditure of muscle energy both by the leg and trunk muscles, while in cycling not only are the leg muscles wholly freed from the work of support and balance, but the trunk muscles are largely relieved from the latter function if the proper sitting posture be assumed. What do I mean by the proper sitting posture? If a person sits so as to ride at ease he should hunch the back somewhat, since this involves the expenditure of much less muscle energy than the bolt-upright position. This is one reason why the back should be well arched in cycling. 2. Man is distinguished from all other mammals by his erect posture. This, while securing him great advantages by enabling him to devote the upper extremities for independent purposes, places him at many disadvantages. If an intelligent extramundane being were to see man for the first time in the horizontal posture it would surely never occur to him that it is natural for man to be erect. There is something incongruous in an animal built on the horizontal plan standing and progressing upon one end of its long axis. Yet this is what man is, and what he does, and it places him at a twofold disadvantage. First, in the matter of progression it leaves him with but two legs to walk with, and the muscles of these two, as already observed, have to expend a great deal of their energy in balancing the body, which from its upright posture is much more difficult to balance than in the case of the quadrupeds. Secondly, the height of the blood column is increased, the influence of gravity on the circulation being correspondingly increased. In particular, as Leonard Hill has so ably shown, there is a tendency for the blood to gravitate into the splanchnic area when the erect posture is assumed, and I cannot but think that the fatigue of standing and walking is largely due to this tendency. It is normally counteracted by the contraction of the splanchnic arteries, by the pressure of the firmly-contracted abdominal muscles on the splanchnic veins, and by the negative intrathoracic pressure, and in cycling it is much reduced and for at least three reasons: (1) the mean distance between the head and the feet is much reduced, and here we have an additional reason why the body and head should incline well forward; (2) the splanchnic veins are compressed by the rhythmic flexion of the thighs on the abdomen, the pressure being increased by the forward attitude; and (3) the aspiratory action of the thorax is increased owing to its increase in mean size, this occurring in all active exercises. That the forward attitude tends to contract the chest is an altogether fallacious notion.

It will thus be seen that there are several reasons why the body should be bent forward in cycling. It may be argued that this attitude, even though physiological, is inelegant. I do not hold this view. An expert rider, properly clad, looks far better bending somewhat forward than sitting rigidly upright, the bend falling in harmony with the curves of the wheels; it suggests ease, grace, and perfect command of the machine. Women pride themselves upon sitting more upright than men, but then few of them have yet learned to ride gracefully; moreover, they have not yet discovered a suitable cycling costume.

I am, Sirs, yours faithfully,

HARRY CAMPBELL, M.D. Lond.

Wimpole-street, W., Nov. 8th, 1897.

A PLEA FOR STRICT CHRONOLOGY.

To the Editors of THE LANCET.

SIRS,—I have recently received the current volumes of the Transactions of various medical societies to which I belong, and I should like to call attention to the way in which their editors confound all historical truth by adding titles retrospectively to past presidents and other worthies. Thus in the list of presidents of the Clinical Society I find under 1869 Sir James Paget, Bart., but he did not receive his title till 1871; under 1871 Sir William Gull, Bart., whereas he was then Dr. Gull; under 1873 Sir Prescott Hewett, who became a baronet many years later; and then under 1881 *Lord* Lister! But the editor of the Medico-Chirurgical Transactions confounds history still more, for he makes Astley Cooper a baronet in 1819 and William Lawrence in 1831 instead of thirty-six years later! Let the societies take example by the College of Surgeons, in whose Calendar no titles are given unless actually existing at the time of election. I am, Sirs, yours obediently,

Nov. 8th, 1897. HISTORICUS.

OVERCROWDING IN FACTORIES AND WORKSHOPS.

To the Editors of THE LANCET.

SIRS,—Would any of your readers be so good as to inform me whether or no a London medical officer of health is bound, legally, by the definition of the term "overcrowding" as laid down under Section I. of the Factory and Workshop Act, 1895—namely, less than 250 cubic feet per person during ordinary working hours, and 400 cubic feet during overtime. If not so bound, what minimum standard of floor and air space—with a nearer approach to the actual physiological needs of the individual—might be adopted (with a fair prospect of success before a magistrate) in the case of toilers in (1) factories; (2) workshops (other than "domestic" workshops which clearly come under the provisions of the Public Health Act); and (3) other workplaces—e.g., laundries.

My reason for raising this vexed question of overcrowding is the noticeable fact that the death-rate from lung diseases amongst indoor workers and other dwellers in densely-crowded (and often ill-drained) districts is in excess of that which obtains in more sparsely populated neighbourhoods.

I am, Sirs, yours faithfully,

Nov. 7th, 1897. M.O.H.

THE EPIDEMIC OF TYPHOID FEVER AT LYNN.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1219.)

To continue the story of the past sanitary history of Lynn, previously to the outbreak at Lynn in 1892 there had been cases of typhoid fever at Gaywood above the intake of the Lynn water. The house where these cases occurred had a box privy, and the contents of the box were emptied in a garden that slopes down to the river, which is only at a distance of fifty yards. Later, during the course of the illness, the dejecta from the patients were emptied into a shallow pit dug at only thirty-five yards distance from the river. This pit was but two feet deep and two feet square. From February 14th to 21st there fell 1·24 inches of rain and snow. It was at the latter date, when the thaw occurred, that the greater part of this water was able to run down into the river, and seven days later the diarrhœa patients at Lynn began to manifest symptoms of enteric fever. By analysis it was also shown that the water of the river is much more polluted after a heavy fall of rain. Naturally a heavy flow of water brings down to the river the manure from the fields, the contents of shallow privies, and the human excrement which is spread out over the gardens. The connexion between the water-supply and the typhoid fever epidemic of 1892 was thus clearly established, and the inhabitants of the town of Lynn had these facts set before them in a masterly manner by Dr. Bruce Low, who reported on the subject to the Local

Digitized by Google

Government Board. After such an experience it would be natural to conclude that the one end and aim of the citizens of Lynn would be to secure at once a proper and safe water-supply.

The town council, acting upon this supposition, commissioned the borough surveyor, Mr. E. J. Silcock, Assoc. M.Inst C E., to draw up a scheme, and this was done with great promptitude. Experiments were made to ascertain whether the yield at Sow Head springs could be increased and it was proposed to take the water at its source in the chalk and bring it direct to Lynn in iron mains. In 1893 the Corporation prepared a Bill, which they hoped to pass in Parliament during the session of 1894, that would give them full powers to deal with the whole question. But, as in 1884, it was necessary according to the law to convoke a meeting of ratepayers. After the lesson taught by the recent epidemic, and after all that has been said and written during the previous years, it was thought the ratepayers would have learnt that it was a matter of humanity, of duty, and even a wise economy to incur the expense of securing a proper water-supply. Nevertheless, the fear of increased rates blinded them to any such considerations. By a large majority the ratepayers voted against the proposed scheme. This seemed so preposterous that a poll was demanded, but the results of the poll were even more disastrous, and by their votes the inhabitants of Lynn clearly showed that they preferred drinking sewage and graveyard water rather than augment the rates so as to procure a pure supply. Thus matters came to a deadlock. The town council was defeated by its own electors, and certainly if the question had been left exclusively in the hands of the majority of the ratepayers nothing whatsoever would have been done. Fortunately Mr. Silcock discovered a way out of the difficulty. If water is to be taken from a river on which riparian rights have been acquired the sanction of Parliament must be obtained; but if water can be abstracted from undefined channels now underground without interfering with any existing water rights, then an Act of Parliament is not necessary, and, what was more important in this case, the ratepayers need not be called upon to approve the project. The Local Government Board was consulted and agreed with this view of the situation.

Under these circumstances it became necessary only to secure a provisional order for the compulsory purchase of two plots of land. On one it was proposed to sink wells and on the other to establish a reservoir. Then it was also necessary to obtain the sanction of the Local Government Board to borrow the required money. Before this was granted in full the Local Government Board held three inquiries. The first took place in March, 1894, and a partial loan was sanctioned in the following September. The money thus obtained only sufficed to sink a well and prove the existence of the water. This work was commenced in November, 1894. At this point the town council made a serious mistake. Instead of entrusting the work to the most competent person they gave the preference to the contractor who made the lowest tender. This is a very common but a fatal failing. The result was that the contractor, instead of completing the work in nine months, had not finished at the end of a year. The contractor then failed and the town had to take up the work where he had left it and complete the wells themselves. They were therefore not terminated till April, 1896, and thus precious time had been lost. But this was not the only difficulty. To get the money it was necessary for the town council to vote in favour of the loans. The councillors individually approved the scheme, but it had been rendered very manifest that it was opposed by their electors, so they hardly dared to vote in its favour. Still, somehow or another, narrow majorities were obtained as detail after detail was brought forward, though on one occasion the situation was only saved by the casting vote of the chairman.

The wells having been dug, the yield of water proved satisfactory, and the next stage was to obtain sanction for the rest of the loan. Application for this was made in April, 1896, and then followed another disappointment. For some unaccountable reason the sanction was not obtained before November 13th following. Though the wells had been completed in April the Local Government Board did not begin their investigation till the following August. Every detail had been previously supplied, yet they were still making inquiries in September. The sanction for the balance of the loan having been finally obtained in November it was necessary to get out the tenders, and the actual work could not be begun before January of this year. Now if no accidents occur, and if the engineers' strike does not interfere with the undertaking, the new water-supply will be ready for distribution in about six months. In the meanwhile there has been a repetition, almost identical in its details though more serious in its effects, of the epidemic of 1892. In February of that year as has been seen there was a fall of 1·24 in. of "rain" in the course of eight days, which brought filth to the Gaywood River and was followed by an outbreak of typhoid fever at Lynn. This year on Sept. 29th a great storm occurred, and in a few hours there was a fall of 2·50 in. of rain. Again a great scouring took place, and the surface storm water brought a large amount of filth to the Gaywood River. Twenty-three days afterwards twenty-six cases of typhoid fever were notified, and it was evident that a serious epidemic had commenced. Surely this second lesson ought to convince the ratepayers of Lynn that it is necessary to have a supply of clean water. Those who were most opposed to the scheme are now seeking to make out that the water is not properly filtered. But it has been explained over and over again that there is no filtering process at Lynn. The water is simply passed through some gravel, which acts as a strainer, not as a filter. Then it is said that the filters, which do not exist, have not been cleaned for many years. The strainers, which do exist, are cleaned every week by forcing water in the contrary direction—that is to say, upwards—so that the mud, &c., is lifted off the surface of the gravel and carried away by an overflow pipe. This straining process does not affect the impurity of the water, but only its appearance. To establish temporary filters of a really effective character would cost some £5000 and require six months' time. By that time the waterworks now in course of construction will, it is anticipated, be finished.

There can be no doubt but that the persistency with which the ratepayers of Lynn have so consistently rejected all proposals to provide a new water-supply was based on the desire to keep down the rates. At the same time, though this was the main motive, it could not be publicly proclaimed. To condemn a town to recurring epidemics so as to save the ratepayers' pockets does not constitute a very good electioneering cry. Other reasons had to be found and were found. In all fairness I am bound to cite these reasons in so far as I have been able to ascertain them. Of course, there is the old familiar argument of people who have lived a number of years under certain conditions, who imagine that they are none the worse and therefore object to expensive alterations. People who speak in this manner ignore those who have not continued to live, but have been brought prematurely to the grave, and they are blind to the dangers which the future may have in store for those who have survived. The argument also that what was endured in the past can be endured in the future has also the fundamental defect that it is not based on fact. The present and the future are not similar to the past. There were formerly fewer habitations on the banks of the Gaywood River, and the water above the intake was not so frequently polluted. Also, the number of inhabitants of Lynn was not so great; therefore, as less water was required a slower process of filtration could be applied. Now the only approach to a serious argument which the opponents of the water-supply schemes could adduce is that the river was kept cleaner and that the methods of filtration were more perfect. As to the condition of the river, doubtless it was somewhat cleaner. Perhaps it was more carefully watched. Assertions to this effect are frequently made, but it is as difficult to prove their accuracy as it is to deny them. In any case there are now more sources of contamination than in the times gone by. As for the processes of filtration, it may without hesitation be affirmed that what was done in the past and what is done now are in both instances absolutely inefficacious. The principal difference is that to-day no pretence at filtration is made. It is emphatically and distinctly stated that there are no filters; there are only some strainers just to keep the dead dogs, the big pieces of wood, leaves, and heavy particles of floating mud out of the water-pipes. This is not filtering, but merely a rough method of clarifying the water. It might well be urged that water ought not to be clarified, as this does not purify it, but only helps to deceive the consumer. If the water was delivered in its natural dirty condition it would not be more dangerous, and the population would more readily understand the necessity of boiling the water and of getting a better supply. Indeed, and in spite of the continued use of

Digitized by Google

the strainers to clarify the water, the opponents of the new water-supply scheme accuse the waterworks committee of striving to render the actual water-supply as foul as possible so as to compel the inhabitants of the town to approve of their scheme.

It is stated that formerly there were filter-beds which consisted of shingle, fine shingle, sand, and charcoal, all resting on some gratings. The water came from underneath and was forced upwards. The filtering material was cleansed and renewed from time to time. This description is accurate except for the all-important fact that the word filter is applied. Then, as now, the water was not filtered, but merely strained. Even if the strainers were then capable of filtering their action would have been destroyed by the constant cleaning which is justifiable for a strainer, but renders a filter inefficacious. The Lynn ratepayers who ignorantly clamour for the cleaning of filters forget, or do not know, that when a filter is cleaned the water must be allowed to run to waste for several days till a film has been formed on the surface of the filter, and it is only when thus dirty that the filter arrests the passage of pathogenic bacteria. The process of upwards clarification was altered because it was found so inefficacious that eels got through and frequently blocked the delivery pipes. Needless to say that a so-called filter which allows eels to go through is scarcely likely to stop the passage of micro-organisms. Therefore, downward clarification was adopted and gravel only employed which was found sufficient for the purpose. That a filter is not intended is proved by the fact that these strainers are cleaned every week. By the present method eels do not get through so easily, but there are complaints about small fish and water-bugs. On one occasion the former borough surveyor, Mr. E. G. Mawbey, Assoc.Inst.C.E., did make an attempt to filter the water and placed in one of the two strainers all the necessary material. But these strainers were much too small for such a purpose, and the amount of water that came through was so limited that it was necessary to promptly remove the filtering material or there would have been a water famine in Lynn.

Finally, it is argued that if the strainers are too small to act as filters large filtering beds could be constructed. If London is satisfied to drink polluted river water, why should not Lynn do the same? The filtering process employed in London has proved satisfactory, why should not the same process be employed for Lynn? Those who thus argue forget that Londoners are not at all satisfied at having to drink river water, that there is always the fear of the filters getting out of order, and that had it been possible to obtain a sufficient water-supply direct from the chalk Londoners would certainly have been much better pleased. This has been done for many great capitals—Vienna, Paris, Rome, &c.; and the Lynn ratepayer who would urge the inhabitants of these cities to drink the water of the Danube, the Seine, or the Tiber would meet with a sorry reception. It is astonishing with what tenacity some of the Lynn ratepayers cling to the idea that the River Gaywood does not merit the aspersions which have been showered upon it by technicians. If, indeed, it is foul, this, they urge, is because it has not been cleaned, or, when cleaned, because the herbs that were cut out of it, have been left on the banks to rot, and the foulness of this decomposing vegetation has flowed back into the stream As a matter of fact, the authorities have not dared to clean the river for many years because they know that impurities are constantly flowing into the water, and they feared that an epidemic would result if the filth in the bed of the river was stirred up. Thus the adversaries of the new water scheme argue that if the river is foul it is all the fault of the waterworks committee, who should have cleaned out the river and shown more energy in proceeding against those persons or villages and hamlets who let their drainage flow into it. Then they also ask whether, after all, the pollution does not take place in the mains rather than in the river.

This latter question is of importance. The subsoil of Lynn is likely to be highly contaminated on account of its porous character, its damp condition, and because the streets, the courts, and alleys are very badly paved or not paved at all, and because there are still many privies in the town, probably as many as a thousand. Then the sewers are badly constructed, leak, and are water-locked twice a day. The pipes that convey the drinking-water through such a soil should be exceptionally sound and should be the subject of constant attention and watchful care. Certainly it will be argued that the pressure in water-pipes is from within. But on this point a great divergence of opinion exists. It is said that when there is a leak in the pipe, though the water from the inside flows outwards, still there may be, as it were, eddies by which some slight quantity of the water outside gets into the pipe. Also the pressure from within the pipes varies considerably, and sometimes the water is turned off altogether, then the foulness surrounding the pipe can easily penetrate. It would be a great misfortune, if when pure water is brought to the town that water became contaminated in passing through the streets. Certainly it would be prudent to examine the mains and branch pipes before introducing the new supply. It does seem like putting new wine into old bottles to bring down from the hills and the chalk through seven miles of new pipes a fresh and pure supply which will be poured under high pressure in the old pipes that are laying in the unstable and dirty subsoil of the streets of Lynn. If some accident should occur the opponents of the new water-supply would appear to have the argument on their side.

With regard to the typhoid fever epidemic of 1892, which should have constituted a sufficient warning to the inhabitants of Lynn, the counter argument is that this epidemic was greatly exaggerated and due to bad sanitation rather than to the water-supply. First it is said we should bear in mind that the town was then suffering from a very severe epidemic of influenza. Cases of intestinal influenza were magnified into typhoid fever and a scare was created so as to promote the new water-supply scheme. The intestinal influenza could be distinguished from typhoid fever by the absence of mortality. Nevertheless, it is not denied that ultimately true typhoid fever was manifest, but still doubts as to its being due to the contamination of the River Gaywood were loudly expressed in 1892 as they are again repeated to-day. There is one useful feature in this opposition to the water scheme. It has helped to draw attention to other sanitary defects in the town. In this respect Lynn is the very opposite to Maidstone. In the latter town no one could speak or think of anything else than the water-supply. To suggest that there might be other contributive causes was certain to evoke expressions of incredulity. In Lynn there are, on the contrary, so many persons anxious to defend the water-supply that some ingenuity is displayed in attributing the blame to all manner of other circumstances. And these other circumstances undoubtedly do exist For instance, the one medical practitioner in the town who has not joined his colleagues in their crusade against the water-supply pointed out to me a house where in 1892 he had attended a case of typhoid fever. At the back there was a privy on ground a yard higher than the patient's room. During the two preceding years complaints had been made concerning this privy, but no measure had been taken to abate the nuisance. On the same day the occupier of the house to which the privy belonged was also attacked by typhoid fever. Several other cases occurred in the immediate neighbourhood of this privy. Further, my informant insisted that the cases of typhoid fever were not evenly distributed over the town, but appeared in clusters as if surrounding some particular local source of infection. If the water had been the cause it is maintained that such clusters would not have occurred. This is an assertion I am not able to verify, as I cannot find a spotted map of the 1892 epidemic. But there is such a map of the present epidemic, and though this map shows that the disease prevails all over the town it is not evenly distributed. For instance, there are more cases at the extreme north and south of the town. The central portion facing the River Ouse has the fewest number of cases, but there are here many business premises and the population is not so dense. It is south of the Mill fleet, one of the four brooks which divide the town, that the greatest number of cases have occurred. Giving off the Windsor-road a number of small streets have greatly suffered. This part of the town was flooded during the great storm of Sept. 29th last. The sewers overflowed and inundated the cellars or basements of these houses. When the water was drained away there remained a foul, thick mud, so that the inhabitants might have been contaminated, not only by the water they drank, but also by the sewage that was brought into their houses. Close by, in the London-road, the main sewer comes from opposite directions and meets at the head of the Windsor-road, and should here take a different course. During the storm, when the two currents met, the force of the shock was so great that the water burst out of the sewer and inundated all the

Digitized by Google

neighbourhood, therefore the opponents of the water scheme urge that it was the flood of sewage and not the drinking-water which caused the epidemic. But inasmuch as there are many cases of fever where there has been no flood, all that can be said is that the fouling of the houses rendered their inhabitants more susceptible.

All this disputation might easily have been set at rest by obtaining a bacteriological analysis of the water. For some unaccountable reason this has not been done. The adversaries of the new water-supply, therefore, have not failed to suggest that if the water was not analysed it was because the authorities knew full well that it was not polluted. The tenacity with which some people in Lynn still maintain that the water is not polluted, though they can see the filth flowing into it daily, is really quite amazing. This persistence becomes amusing when, as another argument in favour of the purity of the water, the inquiring visitor is further informed that Lynn is one of the highest rated towns in the kingdom. The inhabitants of Lynn do not seem to realise that the Freebridge Lynn rural sanitary district, which consists of thirty-three parishes spread over 69,299 acres and had a population of 12,366 at the 1891 census, is in a great measure drained into the Gaywood River. There are constantly cases of typhoid fever in this rural district, and at Grimstead a man died from typhoid fever last July. It will be remembered that one of the three springs that originate the Gaywood River starts from the Grimstead Cemetery. In looking up the records of the Grimstead Church it will be found that in the year 1832 there were 48 burials in this cemetery, of which 26 are entered as due to "blue oriental cholera." It has been argued that the water must be pure because there was no cholera at Lynn in 1849, 1853, and 1865 or 1866. As a matter of fact there were in those years two deaths, seven deaths, and one death respectively from cholera, but there was no epidemic; at the same time there were no cases of cholera on the river bank. In 1832, however, Lynn suffered more severely, but there were cases up the river above the water intake. Yet every precaution was taken. In November, 1831, a committee was formed, including the magistrates and medical men of the town. It was arranged that medicaments should be distributed gratuitously and a building set aside for the reception of cholera cases. The town was divided into districts and committee men visited all the houses to remedy insanitary conditions and report cases of diarrhœa. In spite of all these precautions the cholera invaded the town the following year; but the first death occurred at Grimstead, not at Lynn. It occurred on June 29th, 1832, and the last death was on July 29th, whilst the first death recorded at Lynn was on July 2nd, and the last on Aug. 22nd. Then at Pot Row, which drains into the Gaywood River, there were 26 deaths from cholera in fourteen days. This is a water-logged village beyond the village of Gaywood. There is a sandy subsoil with water four feet below the surface. Every well in the district can be easily polluted, and the inhabitants in their turn pollute the Gaywood River. In the Freebridge rural sanitary district there have been 17 cases of typhoid fever since the month of October, and there was a case at Gaywood before the present epidemic broke out at Lynn. The patient lived within a hundred yards of the river, where there is an old privy attached to the house, and its contents were put on the garden between the house and the river. Last year there were eight cases of typhoid fever in this same rural sanitary district. Thus it will be seen that the Gaywood River, which supplies the drinking water of Lynn, has ample opportunities of being contaminated.

(To be continued.)

THE EPIDEMIC OF TYPHOID FEVER AT CLIFTON.

IT is a very long time since Clifton has been visited by such a severe epidemic of typhoid fever as the one that is now progressing, if, indeed, it ever has; and never, we believe, have the authorities been better able to recognise the seriousness of the outbreak or deal with it in a more energetic manner than on the present occasion. Though there had been cases of typhoid fever notified in Bristol during August, September, and October, they were not more in number than the average, and no suspicion was entertained that an outbreak like the present was likely to take place; in fact, during the week ending Oct. 9th no cases were notified, while only 6 were reported in the week ending the 16th, 3 of these cases being at Clifton. During the next week (ending Oct. 23rd) 18 cases were notified, 16 of these being at Clifton. It was during this week that the blood of some patients suffering from certain indefinite symptoms was sent to the medical officer of health for examination by Widal's test, and in his reply he stated that he believed the disease to be typhoid fever. Within a very short time a considerable number of specimens were sent to him, all coming from cases which presented some difficulty in diagnosis, and in a large majority Widal's phenomenon was observed. The accuracy of the diagnosis was subsequently fully confirmed by the clinical developments of the cases and by a post-mortem examination made on a case which, unfortunately, proved fatal. A large number of notification returns followed, so that in the week ending Oct. 30th 109 cases were reported in Bristol, 100 coming from Clifton, and it is certain that not only have some cases not yet been notified, but that a few mild cases have recovered and so escaped being reported. The notification returns, however, do not show accurately the outbreak of the epidemic in point of time, and by the courtesy of the medical officer of health we are able to give the actual onset of the attacks as reported on the notification returns. The following figures are for the whole of Bristol for the month of October:—Oct. 1st to 3rd, 4 cases; Oct. 3rd to 9th, 15 cases; Oct. 10th to 16th, 38 cases; Oct. 17th to 23rd, 51 cases; Oct. 24th to 30th, 21 cases.

This accounts for 129 cases, in addition to which there are 12 doubtful and obscure cases. As the returns came in and were examined it became evident that only a very small area of Clifton was affected, which fact pointed so clearly to a contaminated milk-supply that the medical officer of health at once endeavoured to discover the farm and the distributor supplying the infected houses, with the following results.

A certain milk distributor (A) in the employ of a dairy company supplied milk from a farm situated near a village a short distance out of Bristol. In this man's round he supplied eighteen houses in which typhoid fever appeared. Previously to Sept. 30th he had taken milk to a lower part of Clifton, and it was in this round that the earliest cases occurred. After that date he supplied milk in the upper part of Clifton, and left the milk at numerous private houses, at a boarding-house at Clifton College (S), and at the house where the bachelor masters live. On Oct. 18th he began to supply another boarding-house at the college (M), and it is in this house that the most recent cases have appeared. A visit to the dairy farm showed a state of things which, to say the least, is scandalous. A stream runs through the village and receives all the sewage of the inhabitants, and after passing the farm runs into the Avon. On the farm was a pump about five yards from the stream, supplying water identical in constituents with that of the stream, and consequently highly contaminated with sewage and swarming with micro-organisms of great variety. This water, which the farmer professed to boil, was used for all dairy purposes, and was quite sufficient to account for the infected milk-supply.

The supply from A did not, however, account for the outbreak in at least eight other houses, but on pressure being brought to bear on another distributor (B) he admitted that he supplemented his supply with milk from A, although this was contrary to regulations. This source of infection was suspected because both A and B entered Clifton by the same route—i.e., over the suspension bridge—but it certainly was the duty of the district council to see that the drainage was conveyed away in such a manner as not to pollute streams which run near dairy farms.

As might be expected, a few cases have occurred in houses not supplied by A or B, but it is quite possible—in fact, it is known in some instances—that the infection was taken at tea parties and other special entertainments, and that occasionally supplies were taken from the infected milk. The disease has largely attacked young people and servants, though adults have not escaped. In the boarding-house at the college (S) 26 cases have occurred and in the other boarding-house (M) 5; in fact, Clifton College has been severely attacked, several masters, a master's wife, boys, and servants suffering from the disease. We are glad, however, to hear that no new cases have been reported recently. The authorities have been put to great anxiety and have taken every measure in their power to prevent the spread

Digitized by Google

of the epidemic, and it is satisfactory to learn that the patients are progressing favourably.

In such an epidemic there is naturally a variety in the severity of the disease; but in most cases the early symptoms were by no means characteristic, the temperature was very erratic, and diarrhœa was often conspicuous by its absence. Testimony must be borne to the great assistance which practitioners have received from the medical officer of health, who on the first intimation that typhoid fever had occurred and that obscure cases of continued fever were prevalent was prepared to examine the blood by Widal's reaction. The blood of over eighty patients has been examined in the laboratory of the medical department of the sanitary authorities, and the reports have in many instances materially assisted in correctly diagnosing obscure cases. We are informed that the primary case—i.e., the one that infected the stream—has not been discovered, but that as soon as the source of infection was found to be the milk from A's farm the supply was stopped.

The notifications during the week ending Nov. 6th were 67, but a large number of these were what may be described as old ones—that is, cases that should have been reported in the previous weeks. The corrected table of onsets is as follows:—

	Cases.		Notifications.
Oct. 1st and 2nd	6	.....	0
Week ending Oct. 9th	23	.....	0
,, ,, ,, 16th	46	.....	6
,, ,, ,, 23rd	68	.....	18
,, ,, ,, 30th	50	.....	109
,, ,, Nov. 6th	2	.....	67
Totals.....	195	.....	200

There are several cases which are known to exist that have not yet been notified. The latest notification returns are up to Nov. 8th, on which day 3 were reported, the same number as on the two preceding days. Twelve cases have proved fatal. The medical officer of health further says that at each point of the inquiry confirmatory evidence as to the original suspected milk has been forthcoming, and it is now quite established that this has been the actual cause of the Clifton outbreak, and the only cause.

THE RINDERPEST IN SOUTH AFRICA.

(FROM A CORRESPONDENT.)

IN spite of all the precautions taken by the Cape Government during the last twelve months, and the indefatigable efforts of the Minister of Agriculture and the veterinary staff under Mr. Hutcheon to check its progress, rinderpest is steadily advancing in the Cape Colony, and almost each day brings news of fresh centres of infection. It is practically certain that the disease will eventually spread through the whole of the colony. Those who have passed through districts which rinderpest has ravaged unchecked are never likely to think lightly of its appalling effects or to be indifferent in their endeavours to carry out any measures which promise a fair amount of success in diminishing its results.

An Object Lesson from the Protectorate.

Some idea of what a terrible scourge this disease is may be gathered from a comparison of the condition of the Protectorate in the beginning of 1896 with that six months later. In January of that year the country was teeming with cattle, and hundreds of ox transport wagons were to be seen toiling along the road between Mafeking and Bulawayo, a distance of over 500 miles, carrying loads at the rate of about 14*s.* per cwt. In July the country did not contain sufficient cattle for even ploughing purposes, and transport had risen to £6 per cwt. over the same distance, and was almost entirely dependent on mules, donkeys, and horses, and the price of transport oxen had risen from about £6 to as high in some cases as £60 for salted cattle. The veld along the road was strewn with putrefying carcasses of dead oxen, and in many parts littered with the contents of stranded wagons—hundreds of wagons standing useless, exposed to the elements and the tender mercy of any passer-by, with no animals to drag them even to the nearest wayside station.

The Origin of the Epidemic.

The plague, according to Captain Lugard in his work on the "Rise of Our East African Empire," appears to have started on the east coast, opposite Aden, and to have spread inland about the end of 1889, probably having been brought there through the medium of infected cattle imported from India, in some portions of the north of which country rinderpest appears to be endemic. It spread through Central Africa till, in March, 1896, it appeared in Bulawayo, whence it was carried rapidly along the southern transport roads to Tuli, on the northern borders of the Transvaal, and to Mafeking, on the north-western border of the colony, reaching the latter place about the middle of April, having travelled the distance of over 500 miles in less than six weeks. The disease soon passed the Limpopo River, on the north of the Transvaal, and steadily continued its deadly march through the Transvaal, and appears now to have traversed the whole of that State from the Limpopo on the north and west to Natal and Swaziland on the east, and has crossed the Vaal River in the Free State, the whole of which State is now suffering from its ravages.

The Story of the Fences.

As soon as the plague reached Mafeking in April, 1896, every effort was made by the authorities to stay the spread of the disease. The officials of the Agricultural Department and the whole available veterinary staff concentrated their efforts in endeavours to confine it, if possible, to that portion of the country. Herds of cattle were shot and compensation paid to the owners, two lines of fences were erected, and cordons of police placed at various points to prevent the movements of infected cattle into non-infected areas. But in spite of all precautions the infection was spread, chiefly by cattle from infected areas in the Transvaal and Free State crossing the border behind the line of defence, and on Oct. 3rd, 1896, it appeared in the Kimberley district and gradually spread through Griqualand West.

The Stand at the Orange River.

A last determined effort to check the inroads of the disease was made at the Orange River. Here a barbed wire fence was erected 1000 yards on the southern side of the river, extending from the south-west boundary of Bechuanaland right along the border of the colony and Free State as far as the Basutoland border, thence along the boundary of Basutoland and the colony as far as the Natal border, and from this point along the Natal and colony border to the coast. Police were placed along the whole line, and all communication between the infected areas on the north of this line and the non-infected areas to the south or colonial side carefully guarded for a distance of about 980 miles. The precautions succeeded for about four months in keeping the plague out of Cape Colony proper, but on March 24th, 1897, an outbreak of the disease occurred in the Herschel district south of the line of defence. The way in which this occurred is interesting as showing how extremely difficult it is to exclude all sources of infection in a country like South Africa. The leader of a transport waggon travelling on the main road south of Aliwal North on the colonial side of the Orange River fence picked up an old sack containing among other things some dried meat and a pair of trousers stained with blood, probably from contact with the meat. The boy put on the trousers without washing them, and the result was that his two leading oxen became sick with rinderpest a few days afterwards and spread the infection to other cattle. The contents of the sack indicated that the Kafir to whom the sack belonged had been working in mines, probably in the Transvaal; and that this sack was the source of infection seems sufficiently probable from the fact that the transport oxen had not been within many miles of the infected area, from which they were separated by the Orange River, at this time in flood. The hope that the disease would be kept out of the colony by the means described had at last to be reluctantly abandoned, and it became evident that all further idea of confining the plague by means of rivers, fences, or cordons of police was futile. The various districts were then placed under the control of committees, who are now endeavouring with varied success to confine as much as possible the spread of the disease. These measures to some extent retarded its progress, but the disease having once succeeded in passing the more efficient barriers that were opposed to its progress, such as the Orange River and its fence, it could no longer be expected that the less efficient means at disposal would long succeed in preventing its advance into the rest of the colony. During the end of 1896 the Cape Government, seeing the appalling spread of the disease in spite of their precautions, and the

Digitized by Google

uselessness of all known remedies, decided to obtain the assistance of Professor Koch, the noted German bacteriologist, and were fortunate in securing his services for investigating the disease and trying to discover some method of combating its frightful results. Thanks to the brilliant discoveries of this investigator, means were placed at the disposal of the Government which promised to a very great extent to reduce to reasonable limits what at one time appeared likely to become a national calamity as far as this colony was concerned. Before, however, proceeding to discuss what these measures were it will be well to describe the disease itself and the symptoms to which it gives rise. The following description of rinderpest is taken from the report by the colonial veterinary surgeon (Mr. D. Hutcheon).

The Rinderpest.

Rinderpest is a specific, malignant, and highly contagious fever, characterised by acute inflammation of the mucous surfaces. It is spread only by communication, directly or indirectly, from sick to healthy animals. It is essentially a bovine disease, though it may be communicated to other ruminants, especially the buffalo and some of the antelopes in South Africa, particularly the koodoo, eland, bushbuck, and duiker; sheep and goats are also affected by the disease, but as a rule suffer very little beyond a slight rise of temperature, although occasionally they die from it. It is characterised by a period of incubation of from three to ten days, and its most prominent symptoms are a rise of temperature and a low typhoid form of fever, which is ushered in by trembling or shivering and twitching of the muscles behind the shoulders and flanks. There is a discharge from the eyes and nose, at first watery, but soon becoming mucous. There is constipation at first, which in a day or two is followed by diarrhœa. The mucous membranes of the eyes, mouth, nostrils, and vagina of the cow are red and inflamed-looking. There is congestion of the skin, and in numerous cases an eruption of pustules on it.

The First Symptom.

The first symptom of rinderpest is a rise of temperature which in inoculated animals generally occurs about the fourth day, often a little earlier. In those animals that contract the disease by infection in the ordinary way the period of incubation is probably longer. The temperature rises from normal (102° F.) to from 104° to 108° or even higher. At the first characteristic sudden rise of temperature there are no visible symptoms indicating that the animal is sick except that close observation will detect that it does not eat so vigorously and appears less lively than usual. By the fifth day the animal will look a little dull, the coat will appear rough, and the appetite will be visibly affected, although it may still feed a little. A rough but comparatively mild cough is very often one of the first indications. The external symptoms appear about the sixth day, when the ears are observed to droop when the animal is standing quiet and undisturbed. A little watery discharge begins to flow from the eyes, turning to thick mucus later, and the eyes appear red and inflamed. There is a slight dribbling of saliva from the mouth and a little mucous discharge from the nostrils. These symptoms gradually become intensified as the disease advances, and the animal stands with its head hanging down and its ears drawn backwards and drooping. The coat is rough, and a twitching and trembling of the muscles behind the shoulders and about the flanks and hindquarters will be observed. The discharge from the eyes, nostrils, and mouth becomes increased; that from the nostrils is sometimes discoloured with blood; and the muzzle presents an excoriated appearance. The mucous membrane lining the mouth shows a bright salmon colour, and a few ulcers may be visible about the dental pad and on the under surface of the tongue; the bran-like eruption on the palate which is described in most works on the subject is rarely met with; the breath has invariably a very fœtid odour. Diarrhœa commences about the seventh or eighth day after infection, or from about the second to the third day after the outward signs become visible. The colour of the fæces may be at first natural, but they generally become of a dirty brownish-yellow colour, as if mixed with bile and mucus, and contain little or no fæcal matter. In some instances the fluid fæces will be discharged involuntarily, soiling the tail and hind legs, the anus being relaxed and inflamed, in some cases even ulcerated; in other cases there is straining and great uneasiness, the animal moving its hind legs and whisking its tail as if suffering abdominal pain. The prostration of strength in serious cases is very marked. The animal walks with a staggering gait when made to move, and when standing its back is arched, with the hind legs drawn under the body. If left at liberty in the open undisturbed the animal seeks the shelter of the trees, where it will lie persistently. The thirst is very great, and when allowed to get to the water the animal will stand and sip away continuously and very frequently die in the water. In many cases the breathing becomes quick and laboured, accompanied by a moaning grunt. In milch cows the flow of milk begins to fall off immediately. The pulse is much increased, and as the disease advances becomes very quick and feeble. Some hours before death the temperature suddenly falls below normal. The extremities and surface of the body become cold and the animal dies in a semi-comatose condition. Death takes place from two to six, or even ten, days after the visible symptoms appear. In many cases after apparent recovery the animal suffers a relapse and dies.

The Diagnosis.

Although typical cases of rinderpest are comparatively easy to diagnose after the external symptoms have become fully developed, still there are a great many other cases in which the symptoms are not very clearly defined, especially in the early stages. The temperature is usually an excellent guide, but even that cannot always be relied upon, as we get a high temperature in other diseases involving the digestive organs. For instance, there are many cases in which the running from the eyes is not very marked and the discharge from the nostrils barely discernible. There is invariably a flow more or less of saliva about the mouth, but we get that associated with congestion of the liver and other derangements of the digestive organs, while a violent diarrhœa mixed with blood and mucus is often the accompaniment of inflammation of the bowels caused by the animal eating certain irritating bulbous plants. In such cases there will frequently be a pinkish colour of the mucous membrane lining the mouth, with the fœtid breath so common in rinderpest. Again, we meet with a great many cases of catarrh which simulate rinderpest very closely except in the colour and character of the fæces. In all outbreaks, in which only one or two animals are affected, it is necessary to make a post-mortem examination, and even then, unless the case is well advanced, the typical appearances presented by the fourth stomach and bowels may not be sufficiently developed to justify one in giving a decided opinion. There is also a large number of very mild cases in which the characteristic symptoms of the disease never became developed, and if it were not that rinderpest is in the herd, or near it, one would not suspect them of having the disease by external examination only.

The Post-mortem Appearances.

The body is generally much emaciated and the orifices are soiled with a dirty discharge, and the carcass exhales a very fœtid odour. The principal and pathognomonic lesions of rinderpest have their seat in the mucous membranes of the digestive passages, the respiratory organs, and the urinary apparatus. The mucous lining of the mouth is congested and covered over with a slimy mucus. It presents a bright salmon colour, but if the beast has been killed and bled before examination this bright pinkish colour disappears. The epithelium is frequently found detached in places, leaving small ulcerated-looking spots. These are met with most frequently on the under surface of the tongue and on the dental pad. The mucous membrane of the fauces and pharynx is the seat of catarrhal inflammation and is covered with a thickened mucous, but sometimes purulent, discharge. The nasal mucous membrane is likewise the seat of catarrhal inflammation, its surface being covered with a muco-purulent exudation, and towards the openings of the nostrils small ulcers are frequently met with. There is very little change to be observed in either the trachea or œsophagus. Slight catarrhal inflammation is sometimes met with in the bronchial tubes with collapse of some of the smaller lobules. Pulmonary emphysema may also be present. The changes in the lungs are neither constant nor pathognomonic, and are secondary as a rule. There are sometimes ecchymotic patches on the endocardium of the heart, and similar spots are met with occasionally on the pericardium, with a little fluid in the pericardial sac. On opening the abdomen the peritoneum is congested and frequently spotted, and there is a variable quantity of yellow serous fluid in the peritoneal cavity. It is comparatively rare to find any pathological changes in the first and second stomachs

Digitized by Google

although a little serous infiltration is sometimes met with under the epithelial lining. The third stomach is generally hard, and the food between the leaves dry and caked. But very frequently, more especially if the sick animal has been allowed to drink large quantities of water, the contents of the stomach are found quite fluid. It is in the fourth stomach and the intestines where the most marked and characteristic changes are met with. The mucous membrane of this stomach is the seat of acute catarrhal inflammation, the submucous tissue is swollen and infiltrated with a serous effusion, especially the rugæ or folds. The mucous membrane is also swollen and its epithelium detached in patches of various sizes, leaving ulcerated sores, more particularly near the pylorus, where these ulcers present the appearance of dark eroded sores with the yellow degenerated tissue remaining in their centres. In the small intestines is found a muco-purulent greyish yellow exudation, in some cases covering innumerable small spots scattered over the mucous membrane of the bowels. In other cases this exudation is found covering almost the whole of the mucous membrane. In more severe cases this presents the appearance of a thick, membrane-like exudation, which in parts forms a complete cast of the bowel. In such cases the epithelium is thickened, softened, and is found detached over small patches throughout the small intestines, leaving the membrane red and granular-looking. Peyer's patches are generally swollen and denuded of epithelium. The changes in the large intestines are not usually so well marked or so uniform. In many cases the inflammation is more in patches, and in the rectum the mucous membrane presents a blood-streaked appearance. The epithelium is swollen and covered over with a muco-purulent exudation, while there is more or less infiltration of the submucous tissue. In many severe cases, however, the large intestines are just as seriously affected as the small with numerous small patches of desquamated epithelium. It is a very curious fact, also, that many of the cases which manifest the most severe external symptoms do not show the most characteristic post-mortem lesions. The liver very often appears congested, and presents a yellowish colour of various tints. In many of the cases, however, the liver is perfectly normal in character and appearance and the bile apparently healthy. The mucous lining of the gall-bladder is sometimes inflamed, especially about the base of the sac, and the bile is thick and curdy looking. The mucous lining of the urinary bladder is sometimes affected also in patches with a little submucous infiltration, and similar appearances present themselves in the vagina of the female. It is not necessary to go minutely into all the post-mortem changes which may be observed in individual cases. The most marked and characteristic post-mortem appearances are those seen in the mouth and upper-air passages and in the fourth stomach and intestines.

The Treatment.

The treatment of rinderpest up to the time of Dr. Koch's discoveries had not been followed by any satisfactory results, although an immense number of remedies had been tried. Mild laxatives, such as two or three ounces of sulphur in two quarts of gruel during the early stage, followed by catechu and opium when the diarrhœa stage is reached, and the keeping of the animals as quiet as possible, sheltered from the sun, and on a limited supply of water, with a little nourishing gruel to drink, is the form of treatment which probably gives a higher percentage of recoveries than any other.

The Mortality.

The various rates of mortality which have occurred appear to depend upon the degree of virulence of the outbreaks. There can be little doubt that during the hot summer weather the disease in many instances assumes a milder form than in the colder winter months. During the progress of the disease through the Protectorate and in the Mafeking district 5 per cent. of recoveries was considered a very high average during the winter months. About the beginning of September, however, when the weather became warmer, 10 and 15 per cent. of recoveries were reported. There was also a great difference between the recoveries on individual farms, varying from 2 per cent. to 10, and even 20, per cent. in exceptional cases. Similar results as regards the effect of dry, warm atmosphere have been recorded in India.

The Modes by which Rinderpest is Spread.

The principal modes by which the disease is spread are: (1) immediate contact of healthy with affected cattle; (2) healthy cattle grazing on the veld where infected ones have recently been or drinking at stagnant pools already poisoned by the secretions and excretions of affected cattle; (3) the conveyance of the infection by wild animals susceptible to the disease into healthy districts; (4) the conveyance of the poison by means of soiled clothes and hands of human beings, and also by animals not susceptible to the disease, who have been in contact with diseased animals or their excretions or secretions; and (5) portions of diseased meat.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Clinical Society.

THE Manchester Clinical Society was established several years ago, and its career shows that it has supplied a want. It is not antagonistic to the Medical Society of Manchester, which, though no longer youthful, still retains the vigour and energy of its earliest prime, but it serves as a useful supplement and possibly as a gentle stimulus to the older institution. The population of Manchester, Salford, and the district round is considerably over a million and implies the presence of a proportionate number of our own profession. It is therefore evident that abundant scope exists for two societies, and that with only one much interesting clinical work must go unnoticed for want of opportunity to bring it forward. The meetings are held in a large room at the Victoria Hotel, where also another room is permanently retained for reading and business purposes. The annual subscription has hitherto been a guinea, which has entitled a member not only to attend the meetings, but also to take out books, an arrangement having been made with Lewis for a large and constant supply. At the recent annual meeting considerable changes were made in the rules and some novel features introduced. The annual subscription is reduced to half a guinea, not to include the use of the lending library. Those who wish to have books from Lewis's Library will pay an extra fee, which is not likely to be more than 7*s.* 6*d.* per member. Tea, coffee, or cocoa may be obtained during the meetings, at which also smoking is to be allowed. It will be interesting to watch the working of this arrangement. Some may doubt the wisdom of these concessions to human weakness, but the busy practitioner just able to "drop in" to a meeting may often find it a convenience and comfort to obtain simultaneously pleasant and, it may be, much-needed refreshment for body and mind, while the soothing influence of tobacco may help to soften down sharp differences of opinion or personal feeling, while its smoke wreaths with their subtle cloud may perhaps veil asperities of manner. Twice a year visitors will be invited to open discussions on given subjects, to facilitate which short abstracts of the papers to be read will be distributed among the members four days before the meetings. After eight years of devoted work Dr. Hill Griffith resigns the honorary secretaryship and is succeeded by Dr. Helme.

Rejection of the Culvert Scheme.

The counting of the voting-papers issued to owners and ratepayers of Manchester in connexion with the resolution of the City Council to seek powers for the provision of a culvert to convey the Manchester sewage effluent to the tidal waters of the Mersey took place on the 30th ult. The result was as follows: against the resolution of the council, 49,069; in favour of the resolution, 20,528; majority against, 28,541—a very decided vote, in consequence of which members of the rivers committee of the corporation have resigned. They may, however, be re-elected. The position is a difficult one for the Council, but it may lead to a more earnest endeavour to solve the problem of artificial filtration. Various schemes will of course be suggested, one of which has indeed been already put forth for a gigantic culvert to go out to sea at the mouth of the River Dee. It is to be big enough to carry off the filthy water from all the towns and villages in its course, and if carried out will no doubt increase the attractions of several favourite resorts, such as West Kirby, Hoylake, and New Brighton. This scheme emanates from the fertile brain of Mr. Marshall Stevens, well known in connexion with the Ship Canal and the Trafford Park Syndicate. But, alas, for any efforts at

Digitized by Google

originality nowadays. One writer in the *Manchester Guardian* says that perhaps Mr. Stevens is not aware that he "proposed the same scheme over twelve months ago," and another seems to imagine that with the aid, in some way or other, of all this sewage the Dee may be deepened and ships floated up to Chester. The march of severe science does not seem to have crippled imagination.

The Cleansing Department.

It is difficult to realise the enormous quantity of refuse that has to be dealt with in a large community. From the report of the cleansing committee of the City Council it appears that during the year ending March 31st the quantity collected and disposed of amounted to 354,364 tons, more than 1000 tons for every working day; while the area of street surface swept and cleansed was 556,472,760 square yards. A considerable part of this refuse is cremated and mortar is manufactured from the clinkers from the destructors and lime ashes. If not utilised they would have to be carted away at considerable cost, whereas there was a profit on the mortar-making of over £1678. During the year 49,342 tons of material were sent to Carrington, but in future a great part of such refuse will be sent to Chat Moss. The farm at Carrington consists of about 400 acres, and the amount charged as rent during the year was £933 1*s.*; all other expenses in connexion with the farm have been debited to the farm account and credit has been given for all revenue derived purely from the farm. It is satisfactory to note that a profit has been made, but as the amount is not stated it may be but a modest one. Next year it is expected that about £4500 will be received in rents from the estate, and the year's expenses correspondingly reduced. At present the outgoings of the committee far exceed the receipts. During the year £99,334 were paid in wages alone, while the sale of concentrated manure, night-soil, street-sweepings, mortar, &c., has brought in £41,080.

Nov. 9th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

John Redhead Wing of the Ingham Infirmary, South Shields.

ON Nov. 6th the foundation-stone of this extension was laid by the Earl of Durham. The wing will provide for an addition of forty-eight beds, which are to be used for the treatment of medical cases and the wing is added in memory of the late Alderman Redhead, who was a warm supporter of the charity. The new wing will necessitate an increased annual expenditure of £1000, but it is anticipated that in so rich a community as South Shields so popular an institution as the Ingham Infirmary will have no difficulty whatever in raising this amount.

Increase of a Poor-law Medical Officer's Salary.

The Tynemouth board of guardians at their meeting on Nov. 4th increased the salary of their medical officer, Dr. E. Brumwell, from £110 to £160 per annum. Dr. Brumwell has filled the post of medical officer to the Tynemouth Workhouse for twelve years, and is to be congratulated upon this appreciation of his services.

Site for the New Infirmary, Newcastle-upon-Tyne.

This question has advanced another, and it is to be hoped has reached its final stage. The corporation, influenced by Mr. John Hall's gift of £100,000, has given to the governor of the Royal Infirmary ten acres of ground on the cattle leazes. It is a magnificent area, and is situated where the building committee and the governor of the infirmary asked the corporation to give them a site. The consent of Parliament has to be obtained in order that the land may be used for the purpose of building. Seeing that the freemen, the corporation, and the infirmary authorities are at one, it is to be hoped that no opposition will be raised before a Parliamentary committee to the transfer of this land. It is now nearly 150 years ago that the present infirmary was founded and built upon land given by the corporation for the purpose. It speaks well for the popularity of the institution that the present corporation should see its way to better the example of its predecessor 150 years ago.

Nov. 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Morison Lectures.

ON Wednesday and Friday of last week the second and third of the Morison Lectures were delivered at the Royal College of Physicians of Edinburgh by Dr. Alexander Morison. The second and part of the third lecture were again devoted to an erudite *résumé* of investigations into the anatomy of the nervous mechanism of the viscera. The greater part of the third lecture was, however, devoted to the physiology of the subject. This gave the lecturer more freedom and allowed both his reasoning and his imaginative faculties fuller scope, the result being that the lecture was much more interesting to listen to and made many of those who heard it wish that they had not to wait for twelve months to have the clinical aspects of the questions discussed submitted to them.

The Medico-Chirurgical Society, Edinburgh.

The first meeting of this society for the winter was held on Nov. 3rd in the rooms of the Royal Scottish Society of Arts. The President, Dr. Argyll Robertson, occupied the chair, and there was a good attendance of members.

Glasgow Obstetrical and Gynæcological Society.

The first meeting of this society was held on Oct. 27th, Mr. Alexander Miller presiding. The following office-bearers were elected for the session: Honorary President, Professor A. R. Simpson; President, Dr. Malcolm Black; Vice-presidents, Mr. Miller and Dr. Oliphant; treasurer, Dr. Lindsay; secretary, Dr. Jardine; reporting secretary, Dr. Russell; pathologist, Dr. Kerr; members of council, Dr. Reid, Dr. Alice MacLaren, Mr. Richmond, Dr. Balfour Marshall, Dr Edgar, and Dr. Thomson. Dr. Jardine showed skiagrams and a pen-and-ink sketch of a Deformity of the Forearm and Hand. Dr. J. K. Kelly showed (1) the Pelvic Organs and Sections of Lung from a case of Deciduoma Malignum; (2) a Left Ovarian Cyst growing into the Ligamentum Latum and a Right Ovarian Cyst growing free; and (3) a Left Tubo-ovarian Cyst which formed a tumour reaching above the umbilicus and a smaller Right Ovarian Cyst. Dr. Edgar showed—(1) Two Ovaries removed by Vaginal Section; and (2) Ovary and Tube removed by Abdominal Section. A discussion afterwards took place on Extra-uterine Pregnancy based on a paper read by Dr. Edgar on April 28th. Dr. W. L. Reid, Dr. J. K. Kelly, Dr. Stark, and Professor Murdoch Cameron took part in the discussion.

The Aboyne Fever Hospital Difficulty.

By a majority of 8 to 4 the Deeside District Committee have decided to refuse an offer by Sir W. Cunliffe Brooks, Bart., of Glen Tana, to relieve the committee of the fee duty connected with the hospital in course of erection, to defray the cost of building already incurred, and to pay the sum of £1000 on condition that the committee keep away from Aboyne water area. The majority held that this offer did not comply with the conditions laid down by the committee and the Local Government Board. The hospital is ready to be roofed in, but some people believe a guarantee in the required form may yet be given.

University of Aberdeen.

Professor Johnston, whose case in reference to Biblical Criticism was mentioned in the leading columns of THE LANCET, ignoring the decision of the Privy Council and the appointment by the University Court of Very Rev. Dr. Gloag as lecturer on the subject mentioned, proposed to give a course of lectures of his own as though nothing had occurred to disturb his position. Professor Johnston, at the end of last month, accordingly endeavoured to deliver an opening lecture in one of the class-rooms in Marischal College, but owing to the uproarious conduct of the medical and other students the attempt was an abortive one. Since then Professor Johnston has attended at King's College with the object of lecturing, but no divinity student has put in an appearance, and Professor Johnston has been left to do nothing but converse for a short time with the amused pressman or two who went in search of a "scene" or anything to make good "copy" of.—The Aberdeen University Court has resolved by a majority to disclaim any idea of repudiating its obligations as to the erection of a new Greyfriars Church in connexion with the extension of the university buildings, and has requested a conference with

Digitized by Google

the town council of Aberdeen on the subject. In consequence of this decision Principal Sir W. D. Geddes has resigned his position as a member and chairman of the Sites and Plans Committee.—A bust of the late Dr. C. Mitchell, Jesmond Towers, is to be placed in the Mitchell Hall, being a gift from his son.

Professor Macewen and the Western Infirmary, Glasgow.

A most important contribution has been made to this controversy in the form of a statement issued by Dr. J. B. Russell, one of the representatives of the Faculty of Physicians and Surgeons on the infirmary board of managers. Dr. Russell does not allude to particular incidents of the dispute, nor does he concern himself with its merely personal aspects. Indeed, his purpose is rather to raise the whole question of the position which the infirmary occupies towards the university professors. With this in view he describes the effect of the agreement under which the infirmary is bound to make "reasonable provision for professors of the university engaged in clinical instruction," and shows that the minimum effect of this is to transfer the patronage of two physicianships and two surgeonships from the managers to the corresponding university chairs. He admits the necessity of some arrangement with the university, but insists upon certain drawbacks inherent in the present plan. By it the available patronage of the managers is seriously lessened, the visiting staff is divided into university and non-university clinical teachers, with the "assumption always existent in the university mind that the university physicians and surgeons can do something in the way of clinical teaching that the other men cannot do," and as the professors are appointed to their chairs *ad vitam aut culpam* the managers are unable to put a time limit to their appointments at the infirmary. These conditions necessarily mean a serious limitation of the power of the managers to secure promotion for the younger members of their staff, and Dr. Russell is evidently opposed to further encroachments of the university on the patronage of the managers. He recalls an attempt made many years ago by the professors of clinical medicine and clinical surgery "to absorb the entire function of clinical teaching for university purposes," and the defeat of this by the joint action of their colleagues and the infirmary board; he also alludes to the attempt of the university to monopolise the gynæcological clinique for the professor of midwifery at the expense of a gentleman older in the service of the infirmary; and he states that the recent appointment of the professor of materia medica and therapeutics to the charge of beds was urged upon the managers by a "strong letter from the principal." Against the allotment of beds "for the elucidation of materia medica and therapeutics" Dr. Russell enters a strong protest. He regards such a decision as "an insult to the existing staff; it put forward a most painful suggestion to the minds of subscribers, and it virtually alienated for ever from the patronage of the managers a physicianship and two wards." It is in the light of these occurrences, Dr. Russell contends, that the attempt of the senate to secure a third ward for the professor of surgery must be viewed. As he phrases it, the senate have overdrawn their account. If the professors of midwifery and therapeutics are to be provided with wards it must be in part at least at the expense of the professor of surgery. In dealing with the question of operating theatres Dr. Russell describes in a somewhat satirical tone the extreme demands made on "structure and administration" by a perfect system of aseptic surgery. Pushed to their extreme limit the infirmary would become a "mere federation of cliniques designated and denominated by autonomous physicians and surgeons." The demands which are being made on the managers are, he considers, in some respects beyond the possibilities at their disposal. Dr. Russell's statement has excited much interest, and whilst the feeling in favour of granting to Professor Macewen every facility for carrying on the work of which Glasgow is so justly proud remains unchanged, there is much sympathy with Dr. Russell's opposition to the attempts of the university to still further invade the patronage of the infirmary managers. His contention that a place on the visiting staff ought to be within the possible attainment of those who, in the dispensary and other subordinate positions, do the drudgery of the institution is recognised as sound policy. If such a result is not possible it is manifest that the infirmary will cease to attract to its staff those who are willing by years of subordinate service to qualify themselves for clinical command and instruction. To proclaim to the junior staff that a record of many years of hard and unremunerated work forms no effective argument against the pretensions of an outsider who happens to be a university professor is a proceeding very unlikely indeed to ensure an abundant supply of capable candidates anxious to enter on the service of the hospital. That university professors are necessarily superior to all other candidates is, of course, a pious belief of their "sisters and their cousins and their aunts," but it scarcely commands the unqualified assent of a more virile constituency. The only other piece of news in connexion with the dispute is the appointment of the Rev. Professor Hastie and Professor Adamson to represent the senate on the infirmary board. These gentlemen replace Professor Cleland and Professor Moir, who presumably in the judgment of the senate failed to urge the university claims with sufficient vigour.

Medical Appointments.

Mr. Peter Paterson, M.B., C.M. Glasg., has been appointed one of the surgeons to the dispensary of the Glasgow Royal Infirmary; his promotion makes a vacancy in the extra-dispensing staff. Mr. A. W. Russell, M.B. Aberd., has resigned his position as physician to the dispensary of the Glasgow Western Infirmary. The term of office of Mr. J. Nigel Stark, M.B. Edin., as assistant obstetric physician to the Glasgow Maternity Hospital having expired the post is advertised as vacant.

Nov. 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Proposed Hospital for Infectious Disease at Blackrock.

AT the meeting of the guardians of the South Dublin Union on the 4th inst. the proposal to establish an infectious disease hospital at Blackrock House was strongly opposed by Mr. James H. North, a well-known house and estate agent, on the grounds that the place is situated in the midst of occupied houses which closely surround it on all sides, making isolation entirely impossible, while the injury to the letting value of the neighbouring property would obviously be very great, the Blackrock township, situated on the seashore five miles from the General Post Office, Dublin, being largely made use of by the citizens as a health resort during the summer months. The situation offers no special advantages for the purpose proposed, while, on the other hand, anyone familiar with Dublin will recognise the fact that there are many sparsely populated districts in its suburbs where a suitable site for such a hospital could be easily obtained. The Local Government Board will doubtless recognise this and prevent further trouble to the residents and owners of property at Blackrock.

Trinity College, Dublin.

The opening meeting of the 128th session of the College Historical Society will take place on the 10th inst., when the auditor, Mr. G. F. Irwin, will deliver an address on "Edmund Burke," one of the early founders of the society. The President, the Right Hon. Lord Ashbourne, Lord Chancellor of Ireland, will occupy the chair, and amongst other speakers Sir William Thomson, the President of the Royal College of Surgeons in Ireland, and Sir Christopher Nixon will address the meeting.

The late Mr. Stamer O'Grady.

An influential meeting of the friends of the late Mr. O'Grady was held at the Hibernian Hotel on the 8th inst., Sir George Duffey, the President of the Royal College of Physicians of Ireland, occupying the chair. Resolutions were proposed or seconded by Sir Charles Cameron, Dr. Grimshaw, C.B., the Rev. Chancellor Tisdall, and others. A committee was ultimately elected and a subscription list opened with a view to perpetuate the memory of the late distinguished surgeon by means of some suitable memorial.

The Belfast Water-supply.

Owing to the prevalence of typhoid fever in Belfast and the criticisms made in reference to the water-supply the Belfast Water Commissioners have very wisely decided to request Dr. Frankland to take samples of the water as supplied by the Commissioners to the consumers and to examine and report on the same. His previous report,

Digitized by Google

referred to in THE LANCET,[1] was with special reference to the water in the various reservoirs.

The Forster Green Hospital for Consumption.

On Oct. 30th, on the invitation of Mr. and Mrs. Forster Green, an immense number of the citizens of Belfast had an opportunity of inspecting this new hospital prior to its being opened for the reception of patients. Situated on the south side of Belfast, in a beautiful district with a southern aspect, this most commodious hospital, towards which for the payment of the land and buildings Mr. Forster Green has contributed £13,150, at present is adapted for forty intern patients, but the administration buildings are so constructed that they would serve for a much larger number in the future. The building is lighted with electric light, and the motor has been utilised to pump up the water-supply for the building. There is a good elevator, and the heating and ventilating on the Kleinson system has been carried out by the Stourtevent Engineering Company, and they have contracted to supply a minimum of 5000 cubic feet of air per hour for each patient. In this admirable hospital, which will be a great advantage to Belfast, the most modern appliances have been adapted to ensure the comfort of the patients. It is hoped that the debt of £5000 against the hospital will soon be wiped out.

The Health of Belfast.

It was reported at the monthly meeting of the City Corporation, held on Nov. 1st, that the health of the city of Belfast is improving and that the death-rate during the previous fortnight was lower than it has been for months past. During the past three weeks the death-rate was 20·6, 18·9, and 18·0 per 1000 respectively. The death-rate from zymotic diseases has also decreased, and last week was only 1·9 per 1000, while the deaths from typhoid fever had fallen from 13 in the first week of October to 4 last week. During the four weeks (Sept. 23rd to Oct. 20th) 354 cases of typhoid fever were notified, 45 of scarlet fever, 42 of simple continued fever, 1 of typhus fever, and 13 of diphtheria. The number of cases of typhoid fever, though still too many, are fewer than in the preceding month and they are not confined to any particular district. From the reports presented by the dispensary medical officers at a meeting of their committee held on Nov. 1st it would also appear that the typhoid fever outbreak is on the decline and is not so prevalent amongst the poor as in the middle-classes.

The Ulster Medical Society.

The first meeting of the present session was held on Nov. 4th, when Professor Symington (the out-going president) resigned the chair to Dr. J. A. Lindsay, President for 1897-98, who delivered his inaugural address on the Problem of the Consumptive Poor. After a few preliminary observations Dr. Lindsay proceeded to make a calculation based on the Registrar-General's returns, the mortality tables of insurance companies, and the experience in other countries, of the probable amount of phthisis existing in the British Islands. He concluded that the number of phthisical patients exceeded a quarter of a million, and that of these at least 200 000 were cases which might in the ordinary course require and seek hospital treatment. The hospitals for phthisical patients and chest hospitals in the kingdom were enumerated and their total number of beds computed at about 1160. As cases of heart disease, bronchitis, &c., are admitted into many of these he did not think the number of beds available for phthisis exceeded 1000, or about 1 for every 200 patients. He thought this lamentable deficiency in accommodation was due to a general feeling of hopelessness regarding this problem and the lack of definite medical teaching and guidance with regard to it. A lucid account was then given of the progress made in other countries in providing accommodation for phthisis. The hospitals for phthisical patients in Germany, France, Switzerland, Austria, Norway, Russia, and the United States were enumerated, and the principles of treatment adopted in Germany by Dr. Brehmer and Dr. Dettweiler were detailed and highly commended. Dr. Lindsay believed that similar methods of treatment were practicable in properly equipped sanatoria in the British Islands, and that such institutions held out a good hope of cure or complete arrest for a certain proportion of cases, and restoration to comparative health and capability for work for a much larger number. He also thought these institutions would be a great service in educating patients in the principles of hygiene and in the best methods of preventing the spread of phthisis. The question of the contagiousness of phthisis was fully considered and the opinion expressed that while the direct transmission of the disease from one individual to another was probably a rare event, yet the malady was infective and usually contracted by the inhalation of pulverised sputum. Special institutions would be of great service in limiting the dissemination of the virus. The prevention of phthisis became more hopeful when the history of the gradual stamping-out of leprosy was considered. This subject was fully gone into, and Dr. Lindsay showed a map giving side by side the leper asylums of the British Islands in the middle ages and the hospitals for phthisical patients of to-day. The contrast told heavily against the present age. Encouragement might be obtained in the fight against phthisis from the fact that the disease was already on the decline, the decrease in twenty years having been at least 20 per cent. The duty of the medical profession was to point out clearly the line of advance which future progress must take. At the conclusion of his address a hearty vote of thanks was given to Dr. Lindsay.

Death of Francis Turnly Gage, M.B. T.C.D.

Great regret is felt in Ballycastle, county Antrim, at the death of Dr. Gage, which occurred at that place on Nov. 4th from hæmoptysis. Dr. Gage, who was the third son of General Gage, studied in Dublin and graduated M.B. of Trinity College in 1890. He had been in practice only a few years in Ballycastle, where, by his skill, kindness, and straightforward character, he won the esteem of all who came in contact with him. He was medical attendant of the coastguards. Dr. Gage, who leaves behind a widow and three young children, was buried on Nov. 6th.

The Belfast Asylum.

At the meeting of the board of governors of the above asylum on Nov. 8th the resident medical superintendent in his report pointed out that it was a matter of regret that when persons became actually insane they were frequently taken to the union workhouse prior to being brought to the asylum, much valuable time being thereby lost. To facilitate the early admission of such cases he proposed to supply the relieving officers of the dispensary districts with admission forms, so that when application was made the patients could be sent direct to the asylum. The medical superintendent thought the proper policy was to facilitate the admission and discharge of patients. The chairman (Professor Cuming, M.D.) said the policy suggested by the medical superintendent was a very wise one generally, but in the case of overcrowding it was desirable not to admit any patients who could be treated in the union infirmary.

Nov. 7th.

[1] THE LANCET, Oct. 23rd, 1897, p. 1032.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Case of Dr. Laporte.

DR. LAPORTE has decided, at the instance of his medical brethren, to enter an appeal against the judgment on which he was sentenced. He has also agreed that the subscription which he at first refused should be opened on his behalf, and all the medical journals have signified their willingness to receive subscriptions, the maximum being fixed at 5 francs. The obstetricians of Paris continue to agitate in his favour; among others M. Pinard opened his course of lectures at the Faculty of Medicine with a discourse which has been a good deal talked about and in which he severely criticised the attitude of the magistrates throughout this affair. Professor Varnier has published in the *Revue d'Obstetrique* the text of the report of the experts MM. Socquet and Maygrier—the report, that is to say, upon which the judge caused Dr. Laporte to be arrested. Professor Varnier discusses this report phrase by phrase, although the publication of evidence in a law case is forbidden by French law. He alleges that the post-mortem examination was made very carelessly and clumsily ("dans des conditions de maladresse extrême") so much so that the experts might well be asked whether the perforations exhibited were not made by their own instruments. Professor Varnier concludes by saying that if a specimen of such a kind had been brought to him as a specimen of traumatic perforation to place in a museum he would have refused it. Up to the present Professor

Varnier has not been prosecuted for his infraction of the law.

The Treatment of Tuberculosis by Euphorbia Resin.

M. Pénières, of Toulouse, has just laid before the Academy of Medicine the results of some interesting work with regard to a new treatment of tuberculous lesions which are amenable to surgical treatment. His plan is to treat tuberculous foci by means of injections of euphorbia resin, the strength being under one milligramme. By this treatment he has cured the masses of tuberculous glands in the neck which are so common in young children, and one great advantage of this plan is that it leaves no unsightly scars and is available for the treatment of tuberculous affections of both bones and joints. M. Pénières cited the case of a young man who was affected with tuberculous disease of both wrist joints. Suppuration had occurred in both the bones and the soft parts. The patient had been condemned to amputation, or at least to a resection, but he is to-day perfectly well. M. Pénières exhibited in support of his statements a series of x ray photographs of the affected parts, before, during, and after treatment. In the first set the bones of the wrist joint were seen to be sewn with little black points just like those in worm-eaten wood; then the holes were seen to be filling up, and finally the bones exhibited normal characters. All the sinuses have healed and the patient, who formerly could not hold a fork or even blow his nose, is now able to resume his occupation as a wood-carver. The action of the euphorbia resin must not be pressed by repeating the injections too often. One injection every eight days or even every fifteen days is generally quite often enough. The best preparation is a very fine emulsion in alcohol of such a strength that one cubic centimetre of the fluid contains one-fourth of a milligramme of euphorbia resin.

The Etiology of Cirrhosis in the Intemperate.

At the Academy of Medicine the discussion on this subject between M. Lancereaux and his opponents still continues. M. Laborde, of the Faculty of Medicine, in a communication the reading of which occupied two meetings, maintained in opposition to M. Lancereaux that the cirrhosis of the intemperate is caused by alcohol and not by the potassium sulphate in "plastered" wines. M. Laborde pointed out that it was almost impossible to find tipplers who confined themselves to wine and that in the countries where wine is either not used at all or only used very sparingly, as in some States in North America, the alcoholic origin of cirrhosis was unquestionable. In Normandy, where the people were far from temperate, M. Laborde had had the opportunity of closely observing forty-five individuals who drank only spirits, and he found by percussion that the livers of all of them showed an enlargement which was the first stage of impending cirrhosis. He was therefore convinced, in like manner with MM. Dujardin-Beaumetz and Audigé, that cirrhosis of the liver is the direct consequence of chronic alcoholic poisoning. The question of "plastering" still remained for consideration. The experiments of M. Lancereaux involved an essential fallacy, for he did not know what amount of potassium salt was really absorbed by the rabbits which he used. M. Laborde believed that this amount was very large. It is well known that potassium salts are rapidly eliminated, that they are not injurious except in very large doses, and that such deleterious action as they have is exerted, not on the liver, but on the heart. M. Laborde believed that rabbits were unsuitable for such experiments, as they were extremely sensitive to mineral poisons, and in making an investigation of the subject, on which he has been for a long time engaged, he followed a course which promised more reliable results. He gave wine to two dogs—wine containing 2 grammes of "plaster" per litre to one of them and natural wine to the other. These two dogs had as much as 500 grammes (17 oz) of wine every day, and this large quantity was continued for from fifteen to twenty days, when their appetite was completely lost, and the experiment was stopped for fear that they might die. No symptoms were observed beyond those of the ordinary inebriety due to wine; there was no apparent action of the potassium salts. M. Laborde then varied the experiment by omitting the wine and giving to a dog in fifteen days a total quantity of potassium bisulphate equivalent to 80 grammes (nearly 3 oz.) for an average adult man. The dog's health continued perfectly good. It must also be borne in mind that everybody took in his daily food from 5 to 7 grammes (from 75 to 105 grains) of potassium salts, and at this rate cirrhosis ought to be universal. In M. Laborde's opinion M. Lancereaux erred when he asserted that alcohol was not the cause of cirrhosis of the liver in the intemperate, and his views were not only at variance with the results of careful observation and experiment, but, more than this, they constituted a real danger by encouraging the belief that wine was more injurious than spirits. The enemy which ought to be always and everywhere guarded against was not "plaster" and was not wine, but was spirituous liquor. M. Lancereaux, in reply, confined himself to repeating the statement that all cirrhotic patients in Paris were wine drinkers. By giving potassium bisulphate to rabbits he had produced nothing but very well-marked cirrhotic lesions. The cirrhosis of the intemperate existed long before the modern development of spirit drinking. Alcohol caused various lesions, but these lesions never had cirrhosis as their fundamental process.

Nov. 9th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Dr. Giuseppe Levis.

THIS eminent consultant, who died at Udine on Sunday morning, the 24th ult., will be greatly missed in Milan, where he was for years the Medico Primario of the Ospedale Maggiore and presided over the Istituto Antirabbico. In the cholera epidemic of 1884 his efforts in concert with Dr. Todeschini to mitigate the scourge and to guard the city against future attacks are still gratefully remembered by the Milanese. Besides his merits as a practitioner he had rare gifts as a lecturer, and attracted to his clinique not only students but graduates by his power of luminous exposition and vivid and impressive statement. Since 1895 he had suffered from diffused arterial sclerosis aggravated by aneurysm of the external iliac artery, and latterly by hepatic dropsy due to cirrhosis. For this paracentesis was three times practised with only temporary relief. Last summer he was under Professor Grocco's care at Montecatini, but was found in too hopeless a condition to offer any chance of recovery. In fact, Professor Grocco, shortly after seeing him, sent him back, escorted by an assistant, to Udine, where in the house of his daughter he died.

The English-speaking Practitioner in Italy.

At the last General Medical Congress held here it was moved and unanimously carried that foreign medical practitioners professionally engaged in Italy should undergo a State examination or qualify at one or other of the Italian schools in order to legalise their practice. In consequence of this step a deputation of the English-speaking practitioners has just waited on Signor Serena, Under Secretary of State for the Home Department, to protest against such action. His Excellency announced in reply that arrangements in the direction proposed by the Italian Medical Congress had not yet been taken, but that in any case the Government before giving legal effect to the innovation contemplated by the Congress would put itself in diplomatic communication with the Governments of the other Powers (Great Britain included), with a view to obtaining for Italian practitioners in those countries the same privileges enjoyed in Italy by foreigners. The matter will probably rest there. It is said that foreign dentists, against whom the edict referred to in my last letter has now gone forth, in the event of their being "contumacious," are to be denounced to the judiciary authority. This is a very hard measure for the practitioners of a sister profession and singularly ill-advised as regards the interests of Italy herself. The presence of an English-speaking dentist in her chief centres of foreign sojourn is one of several attractions for the Anglo-American world, without which these places would in great measure cease to be resorted to. Italy, of course, must be credited with knowing what is best for her own advantage and to "order her house" accordingly; but the exclusion of the English-speaking dentists from her cities cannot but strike the outer world as in more ways than one a suicidal step. By the admission of Italians themselves these practitioners possess in their home qualifications an even higher guarantee of professional training and efficiency than any to be found in Italy, while it is an open secret that no Italian when he can afford the choice prefers a compatriot dentist to one imported from America or the British Isles. There

Digitized by Google

is, however, another feature in the circular to which I alluded affecting a still more considerable public than that professionally interested in dentistry—I mean the practitioners of medicine. The Marchese di Rudini, in his address to the prefects, sets out by reminding them that Article 23 of the "Legge sulla Sanità" at present in force forbids the foreign medical graduate from practising unless, in addition to his home qualification, he possesses an equivalent one of some recognised Italian school. Article 140 of the "Legge" of Nov. 14th, 1859, he proceeds, confirms the above, but—the words that follow must be given textually—"eccettua da tale divieto i medici ed i chirurghi stranieri espressamente chiamati per casi speciali e quelli che esercitano la professione presso i soli forestieri" (it excepts from such prohibition the physicians and surgeons of foreign nationality who are expressly called in for special cases and those who exercise their calling among foreigners only). It is primarily on the ground that this second "Legge" makes no mention of "dentists" that the Minister of the Interior would exclude those of foreign nationality from practice, thus falling back on the letter of the law to the ignoring of its spirit. Conscious apparently that this is not a high-minded or statesmanlike proceeding His Excellency goes on to justify his mandate by the argument that "degrees" for special departments of medicine and surgery being now compulsory in Italy, and that "dentistry" being a department of surgery, the foreign dentist, not being a medical graduate, cannot avail himself of the privilege of the foreign physician or surgeon and must take an Italian degree or forfeit the right to practise even among his compatriots. This looks very like quibbling, to say nothing of the fact already noted that qualifications in dentistry are commonly held by Anglo-American practitioners in that department implying as good a preliminary training in medicine as that of any holder of an Italian dental degree. British and American odontology, however, may be trusted to vindicate its own rights, and its medical sister can only wish it Godspeed. Meanwhile it is satisfactory to have the Marchese di Rudini's re-affirmation in so recent a document of the right of the English-speaking physician and surgeon resident in Italy to form a *clientèle* among his compatriots in that country, strengthening as it does our impression derived from Signor Serena's answers to Dr. Santini last summer that the Italian Government has no immediate desire to legislate in Dr. Santini's sense, and, by passing sentence of banishment on the English-speaking practitioner, to deter from sojourning in Italy that Anglo-American world from which her needy and sorely taxed population derives so essential a part of its income.

Report of the Italian Commission on the Pestis Bubonica.

Dr. Alessandro Lustig, Professor of General Pathology in the Florentina Istituto di Studi Superiori, in concert with Dr. Malenchini, Dr. Galeotti, and Dr. Levi, experts in pathology and bacteriology, also of the Tuscan school, was deputed by the Italian Government to conduct a series of experiments, first at home and then in the Bombay Presidency, with a view to discover a "vaccino contro la peste bubbonica," as the terms of their mandate express it. Since their return from India in September Professor Lustig has been engaged in drawing up a report of their work; and now that it has appeared it will interest your readers to have a brief, but adequate, summary of its tenour. The British authorities, says Professor Lustig, were most liberal in their endeavour to facilitate the object of the Commission. Their assistance was all the more welcome, for, says Professor Lustig, the natives put every difficulty in the way of his procuring the "materia prima" of the pathologist—the dead subject. A strange rumour, credited by the poorer classes, came to the rescue. During the epidemic a fanatic had besmirched the statue of the Empress-Queen and, by a coincidence which profoundly impressed the popular imagination, from that day the "pestis bubonica" raged with increased destructiveness. It was then declared that the only check to its ravages would be the "sending to London of a thousand Hindoo livers"—a placebo to the indignant British which multiplied the number of necropsies! Professor Lustig and his colleagues availed themselves of the opportunities thus presented. They obtained the "cadavera" required and were not long in coming upon the bacillus of the disease. This, he says, opposes (fortunately) a feeble resistance to the action of disinfectants; and following up his experiments, mainly on rats and apes, he found its mode of entrance into the organism was by the skin and by the mucosa of the respiratory and alimentary apparatus. Often it stops there; but oftener still it passes directly into the circulation. The "bubonic form" is not necessarily that which it most frequently assumes; the "pestis" itself, indeed, is one of those maladies which may be combated by cleanliness, disinfection, energetic and radical, and, above all, by isolation of the patient, real or suspected. Professor Lustig proceeds to describe his first experiments in the direction of "vaccination." A Russian colleague sent him some cultures of noteworthy virulence. With these he began his investigations in concert with Dr. Galeotti. He reproduced the various pathological forms which he had obtained, inoculating milligrammes of the culture by different channels, either subcutaneously or into the veins or into the abdominal cavity of animals highly responsive to the morbid agent, especially sewer rats. Finally, he succeeded in immunising these rats and other animals so as to render them wholly and persistently proof against the most virulent plague-inducing bacillus. In doses of 8·35 milligrammes the vaccine proved fatal to the rat; injected, however, in smaller doses under the skin and dissolved in alkaline water the vaccine produced only a slight malaise for a day or two. "It is," says Professor Lustig, "innocuous for man. Neither I nor Dr. Galeotti, nor the others who underwent its influence, after an injection of two milligrammes of the vaccine under the skin felt any serious disturbance except a mild febricula for two days and a slight redness of the inoculated part. The most robust persons responded feebly to the vaccination, the less robust somewhat more energetically. The vaccine does not contain 'bacilli pestiferi,' living or dead, and may be preserved dry even for months." But the object of Professor Lustig's inquiries was to ascertain what action both the "vaccine" and the serum exerted on man and on the animals most akin to him. It was, therefore, necessary to repair to the regions infected by the plague. At the end of May accordingly Professor Lustig, Dr. Malenchini, Dr. Galeotti, and Dr. Levi set out for India, and of the tenour of their experiments there and the results yielded I will give some account in my next letter.

Nov. 7th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Legal Sanction of an Unqualified Practitioner.

A CELEBRATED statesman once characterised Austria as the country of impossibilities, and the description is to some extent justified by a recent occurrence. In Upper Austria there are a great many persons of the peasant class who, although they have not studied medicine, nevertheless take on themselves to attend patients, and the provincial government, consisting of adherents of the clerical party, has just addressed a petition to the Emperor praying that permission to practise (*venia practicandi*) might be granted to one of these unqualified individuals. Incredible as it may appear, the request has been complied with, the consequence being that a peasant who never studied either anatomy or any other branch of medicine is now a legally recognised medical practitioner. The President of the Upper Austrian Medical Chamber has energetically protested against this disregard of the law, and many other medical chambers will also do so, but the present political situation makes it impossible to hope that these protests can be successful, for the permission has been granted at the instance of Dr. Ebenhoch, who is one of the most influential supporters of the present Government and is president designate of Parliament.

Streptococcic Toxin and Anti-streptococcic Serum.

Dr. Schenk has published in the *Klinische Wochenschrift* an interesting account of experiments made by him with streptococcus cultures. He found that the effects produced on rabbits by identical quantities of such cultures were far from being uniform. He also made a series of experiments in which virulent injections were given twenty hours after injections of serum, the result being that of sixty rabbits so treated twenty-three survived. These experiments might be called prophylactic; in curative experiments, on the other hand, only two animals survived out of twenty-one. Dr. Schenk also investigated the relation of the streptococcus to erysipelas. As intra-peritoneal and subcutaneous injections of virulent fluids caused only trifling

Digitized by Google

local changes he experimented on the ears of rabbits and came to the conclusion that it was not possible to produce erysipelas with Marmorek's streptococcus, although it may be produced by the streptococci obtained from a phlegmon. In the experiments on the prophylactic or protective power of anti-streptococcic serum 1 c.c. of it was injected into the ear of a rabbit, and this was followed by an injection of 1 c.c. of streptococcus fluid in from sixteen to twenty-four hours; the result was a slight erysipelas; and the same was the case with a second rabbit which was injected with 2 c.c. of serum and 1 c.c. of streptococcus fluid. In a further series of similar experiments there were three deaths in cases in which the quantities of serum injected were respectively 1 c.c., 2 c.c., and 2 c.c, the quantity of streptococcus fluid being 1 c.c., so that the serum obviously failed to prevent infection. According to Bordet there is a morphological property of streptococci which deserves attention, some that are found in the cardiac blood of rabbits having a capsule and being larger than those which have no capsule.

Treatment of Glaucoma.

The *Klinische Wochenschrift* recently contained a short report on the treatment of glaucoma by resection of the superior cervical ganglion as practised by Dr. Jonnesco. He performed this operation on a man, fifty years of age, who had been suffering from glaucoma for six years, and had lost his sight two years previously. The result was that the high intra-ocular pressure immediately became subnormal, and on the second day vision was so far recovered that the patient could count fingers at a distance of two metres (6½ ft.) and could see to walk about by himself. Dr. Jonnesco has obtained equal success in two other cases.

The Goldberger Prize.

The Vienna Medical Society has awarded the Goldberger Prize of 1000 gulden (about £82) to Dr. Ruhemann, of Berlin, for his pamphlet on the question, "Is Catching Cold a Cause of Disease?"

University Intelligence.

A monument to that renowned surgeon, the late Professor Billroth, will be unveiled on Nov. 7th; the principal speaker on this occasion will be Professor Gussenbauer, who was formerly an assistant to Professor Billroth. — Professor Gruber, the famous otologist, celebrated his seventieth birthday on Oct. 16th.

Nov. 6th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A New Test for Typhoid Fever.

THE Health Board of New York claims that a medium has been found in which the typhoid bacillus will thrive, but in which the colon bacillus will not. Typhoid germs are to be found only in the intestines, if at all. Unfortunately the colon bacillus haunts the same region and resembles the typhoid bacillus very closely in appearance, but is absolutely harmless. If, therefore, in matter thrown off from a patient's digestive tract either species is found it is very difficult to tell of which sort it is. Dr. Hiss thinks that he has discovered a test, and the Health Board is going to adopt it officially. The test consists of a culture medium in which typhoid germs will multiply and the colon bacillus will not. The culture is composed of gelatin, agar, glucose (to make the mixture ferment), salt, and Liebig's food. Typhoid germs grow in it and the colon bacillus does not. In actual practice a minute quantity of the semi-fluid matter sent for examination is taken off on a loop and is placed in a small vial containing the culture. Eighteen hours is sufficient time for the bacilli to grow, and a statement of results will reach the medical man in thirty-six hours after he has sent a specimen to the laboratory. At the end of eighteen hours a small portion of the culture is spread on a glass plate which has a glass cover. In a short time the appearance of this plate will give the information sought in showing if there has been any growth. If there is growth it is a case of typhoid fever; if not probably no typhoid fever exists.

The Increase of Suicide.

It appears from a recent paper that the suicide record of the United States since 1890, according to recent statistics, stands as follows: 1890, 2040; 1891. 3531; 1892, 3860; 1893, 4436; 1894, 4912; 1895, 5750; and 1896, 6520. The census of 1880 furnishes us with the number of suicides in that year—2511; but the census of 1890 contains no information upon the subject, the word "suicide" having been omitted. It appears certain that in each 100 000 deaths from specified causes 253 in 1860 were due to suicide, 273 in 1870, and 331 in 1880. These figures, however, give no idea of the actual number of persons who voluntarily ended their existence during the years named; they merely tell us of the number of cases of suicide which were discovered.

Hot Weather and Crime.

Officers of the Weather Bureau have undertaken an investigation of the relation of the weather to crime. Taking the whole country during January, February, and March there were in even numbers 1200 suicides reported in the United States, while in July, August, and September there were 1600. In the same period there were 1700 murders in the cold term, as compared with 2500 in the three hot months. There were 50 persons hanged or lynched in the three cold months, and 113 hanged or lynched in the three hot months.

The Causes of the Decline in the Average Income of General Practitioners of Medicine.

Dr. Charles Phelps, President of the New York State Medical Association, states that the earnest effort made before the last legislature to obtain relief from certain abuses of medical charity was proof of the general diminution in the incomes of physicians, particularly in this city. But this was only one cause; there were others, and it should be remembered that medical practice, like other things, was largely regulated by the well-known principle of supply and demand. It was also easily demonstrable that the amount of sickness in our community had notably diminished. This increased healthfulness even the public was now willing to admit was largely due to the advances made in the bacteriological and pathological laboratories and to a better control over disease by the proper sanitary authorities. Thus, epidemic dysentery had become unknown here and variola was practically unknown. The maintenance of a reasonable standard of purity for milk and proper supervision of plumbing had done much to diminish gastro-intestinal disorders. The effect of the improved cleanliness of the streets on the public health was, in his opinion, problematical. Among other causes mentioned were the general depression, the want of proper adjustment of fees to the income of the patients, the business methods in vogue at the present time, the more complicated mechanism for the treatment of disease, and the increasing custom of sending patients to sanatoriums and hospitals.

Vacation Schools.

These schools minister to the all-round development of the children, for the large playrooms are utilised for calisthenics; the morning half-hour devoted to dancing is sure to find light hearts and feet. One summer all the children were taken, on successive days, under the care of their science teachers, to the ocean homes of the association, where the day was spent in collecting various objects incident to the seashore. Another year they were taken, under competent guidance, to the Museum of Natural History. There is no reason why this side of the work should not be immensely extended in order to make more available the resource of museum and art gallery, because we are only beginning to utilise the social and educational resources of our cities. There is no reason why the very school buildings should not be used more in the evenings, under proper restrictions, because there are many kinds of meetings and entertainments for which they would be available.

Cruel Treatment of Animals in Transportation.

The New York State Society for the Prevention of Cruelty to Animals states that during the past year at Buffalo 16,000 sheep and hogs had been taken out of the cars dead, and more than 8000 had been removed at the same place in a diseased or disabled condition; moreover, these animals were sold for public food and consumption. The coöperation of the association is asked in preventing the cruelties now imposed on these animals while in transit.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Curative Value of Calmette's Anti-venomous Serum in the Treatment of Poisoning by Australian Snakes.

AT a recent meeting of the Medical Society of Victoria Dr. C. J. Martin read a very able and interesting paper on the above subject based on a number of very careful experiments. He showed that the venoms of all Australian snakes contain at least two proteids; one is coagulated and rendered inert by heating to 85° C., and the other is not coagulated even on boiling. It is, however, sensitive to heat, and even momentarily boiling it diminishes its toxic property and prolonged heating destroys it. The two constituents can be isolated by filtration through a film of gelatin supported in the pores of a porcelain filter. The coagulable proteid destroys the blood corpuscles and the continuity of the capillary walls, produces intra-vascular clotting if reaching the circulation with sufficient rapidity, and is a powerful poison to cardiac muscle. The non-coagulable constituent has none of these properties, but affects particularly nerve cells, those of the respiratory centre being especially susceptible. Cobra venom consists very largely (98·25 per cent.) of an uncoagulable proteid similar in action to the one in Australian snakes, consequently it would be expected that Calmette's serum from an animal immunised against cobra venom would have a diminished value against the mixed venom of Australian snakes, although Calmette affirmed that it was equally valuable as a remedy against the poison of all snakes. The result of Dr. Martin's experiments showed that the serum possesses some slight immunising power against the venom of the tiger snake when administered intravenously and one hour before the inoculation of the poison. Injected hypodermically before or coincidently with the venom the animals (rabbits) died. The effect on the different constituents separately was then tried and he found that against the uncoagulable element the serum has a decided protective influence when injected in considerable quantity directly into the circulation just before the poison is inoculated. This power is so slight that the serum is practically valueless as a remedial agent. Dr. Martin also suggests that antitoxin remedies of all kinds, as diphtheritic antitoxin, should be introduced directly into the circulation instead of under the skin, whence they may not be wholly absorbed for twenty-four hours.

The Tuberculin Test for Cattle.

Tuberculin has been used in New South Wales for about two years to detect tuberculosis in cattle, and in the opinion of the President of the Board of Health with great advantage. It is not infallible, but the percentage of errors when properly used is small. Many of the unsatisfactory results arise from disregard of details in its use. The Board of Health has issued a number of rules to be observed in using tuberculin and also a form of record. It is hoped that uniformity in method will thus be secured, and after a time it will be possible to ascertain from the records precise results as to the value of the method.

Food Standards.

The Board of Health of New South Wales has recommended the adoption of certain standards for milk, butter, tea, vinegar, and spirits, with a view of simplifying conviction in cases of adulteration. The following are the standards recommended:—

"Milk shall contain not less than 12½ per cent. of genuine milk solids, of which at least 3½ per cent. shall be butter fat; the milk solids to be obtained by drying any convenient quantity of the sample on a water bath for three hours until constant in weight. Then upon subtraction of 3½ per cent. of fat the remainder shall be taken as the coefficient of 'solids not fat,' and shall be at least 9 per cent.

"Butter shall contain not less than 83 per cent. of genuine butter fat.

"Tea shall not contain more than 8 per cent. of mineral matter calculated on the tea dried at 100° Centigrade, of which at least 3 per cent shall be soluble in water, and the tea as sold shall yield at least 28 per cent. of extract.

"Vinegar shall contain not less than 3 per cent. of acetic acid ($C_2H_4O_2$) and not more than one-thousandth part by weight of sulphuric acid.

"Spirituous liquors, brandy, whisky, and rum shall not be more than 25 per cent. underproof. Gin shall not be more than 35 per cent. underproof."

New Offices for the Board of Health of New South Wales.

On Sept. 20th the Board of Health of New South Wales moved into their new premises recently erected at the corner of Macquarie-street and Albert-street, Sydney. The building is very complete. On the basement is an open way by which ambulance waggons can be brought into a courtyard, into which open isolation rooms for infectious cases and the rooms where patients are seen prior to admission and removal to the Coast Hospital for such cases. On the ground floor are the offices of the Board. The first floor is devoted to the Government analyst, who is provided with a large laboratory. The veterinary staff is also located on this floor. The Government bacteriologist has a very complete laboratory on the second floor, with rooms above for experiments on animals. The building was erected under the direction of the Government architect, assisted by the Board of Health, and has cost about £10,000.

River Pollution in Melbourne.

A deputation waited on the Board of Public Health of Kalma on Sept. 22nd to ask the Board to take some steps to remedy the pollution of the Saltwater River. A number of noxious trades were carried on along its banks and much blood and offal found their way into the river. The chairman replied that little could be done until the underground sewerage was completed, and a Bill was being drafted to deal with slaughter-houses.

Peculiar Action against a Medical Man.

On Sept. 8th a medical man, of Sydney, was sued for £500 compensation by a publican for having, as was alleged, used his hotel for immoral purposes. The statement of the plaintiff was that the gentleman brought a woman to his hotel and engaged a room there. For the defence the doctor denied having engaged the room, and said that the woman was a patient and only seen professionally. The plaintiff admitted that he was an uncertificated insolvent, and that his licence at a previous hotel had been opposed by the police. The jury found for the plaintiff and awarded 20*s.* damages.

Action against a Medical Man for Reporting a Case as Typhoid Fever.

At the Sydney District Court, on Sept. 9th, a dairyman sued Dr. Gwynne-Hughes for £200 damages for alleged unskilful, improper, and negligent treatment. The plaintiff stated that Dr. Gwynne-Hughes was called in to see his daughter, and that he diagnosed the case as typhoid fever and caused her removal to the Coast Fever Hospital, reporting the case as such. The Board of Health thereupon cancelled his registration as a dairyman and his dairy was closed, causing him considerable loss. The medical officer at the Coast Fever Hospital diagnosed the case as one of congenital heart disease, and on the patient's death two days afterwards signed a certificate that she died from heart disease. In his evidence the medical officer said that he would not swear that the child might not have had typhoid fever in an early stage. No post-mortem examination was made. A verdict with costs was awarded in favour of Dr. Gwynne-Hughes.

Sympathy with Dr. E. J. Gurdon.

A well-attended meeting of the medical profession was held in Melbourne on Sept. 23rd to express sympathy with Dr. E. J. Gurdon, who was recently subjected to a vexatious and expensive action at law (as mentioned in THE LANCET of Oct. 30th). Unanimous resolutions were passed sympathising with Dr. Gurdon. A subscription list was opened and all medical practitioners in Australia were asked to contribute towards defraying Dr. Gurdon's expenses.

Sept. 25th.

Obituary.

THOMAS GOLDESBROUGH STOCKWELL, F.R.C.S. ENG.

BY the death of Mr. Stockwell on Nov. 2nd an honoured name is removed from the roll of the medical profession of Bath, in which city he was born in 1823, his father being a medical man who had settled there the previous year. Mr. Stockwell was entered as a student of medicine at the Royal United Hospital, Bath, in 1842, and there received his first lessons in surgery from such capable surgeons as Norman and Brown. Thence he proceeded to St. George's Hospital, London, and became a Member of the Royal College of

Digitized by Google

Surgeons of England and Licentiate of the Society of Apothecaries in 1845. After qualifying he returned to Bath, joining his father, and eventually succeeding him in practice. In 1855 he passed the examination for the diploma of F.R.C.S. Eng. Mr. Stockwell was appointed medical officer to the Eastern Dispensary and in 1860 surgeon to the Royal Mineral Water Hospital. Five years later he became surgeon to the Royal United Hospital. This appointment he held until his death, and for many years he had a large practice in Bath and the country round. His sound common sense and his ready resource eminently fitted him for surgery in the days when instruments and apparatus were not so perfect as they are now. Dexterity without showiness characterised his operations, and his results were good. The storm and strife of public affairs had no attractions for him, but in the family circle he was genial and hospitable, and his kindly presence will long be missed by rich and poor alike in his native city.

CHARLES WETHERED, M.R.C.S. ENG., L.S.A.

THE news of the death of Mr. Charles Wethered will be received with regret by many of the inhabitants of Stroud, where he was in practice for many years. He was born in the year 1827, and received his medical education at University College, and qualified in 1848. He passed most of his life at Stroud, where he was surgeon to the General Hospital, and when he retired from practice he carried with him the general respect and esteem of his many friends and patients. The last few years of his life he spent on his estate near Moreton Hampstead in South Devon. His great relaxation was the study of architecture and archæology. He was an intimate friend of Viollet le Duc, and his book, "The Works of Viollet le Duc in Connexion with the Historical Monuments of France," attracted much attention. He was made an Honorary Associate of the Royal Institute of British Architects, and published some contributions in the Transactions of that society.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Gadaud, formerly in the French Cabinet.—Dr. Paul Güterbock, *privat-docent* of Surgery in Berlin with the rank of Professor, at the age of fifty-four years. His chief work was connected with the surgery of the urinary organs. He was also much interested in the History of Medical cience.—Dr. Aurelio Silvestri, Lecturer on Ophthalmology in the Florence School of Medicine.—Dr. Arthur Scheffer, formerly Professor of Chemistry and Medical Physics in the University of Kieff.—Dr. St. Danillo, *privat-docent* of Psychiatry in St. Petersburg.—Dr. Shukoff, a St. Petersburg neurologist.—Dr. Alphonse Albert, a much-respected Liége practitioner, at the age of ninety years.

BEDFORD MEDICAL SOCIETY.—The quarterly meeting of this society was held at the Bedford General Infirmary on Oct. 28th, Dr. G. P. Goldsmith being in the chair.—Dr. Goldsmith showed a Uterine Myoma which he had removed.—Mr. Nash showed (1) a boy with Macrodactylism affecting the Second and Third Toes and also a Skiagraph of the same; (2) an infant with Arrested Development of the Right Eye and Congenital Fissure of the Right Nostril; and (3) a boy on whom he had performed Tarsectomy for Severe Talipes Varus.—Dr. Hartley opened a discussion on the Use of Antipyretics in Reducing Fevers, which was carried on by Dr. Goldsmith, Mr. Philips, Mr. Sharpin, Dr. Waugh, Mr. Cock, Dr. Ross, and Mr. Nash.—Dr. Ross read notes of a case of Laminectomy for Cervical Paraplegia. The patient fell on to his head and immediately lost power in his arms and legs. He was admitted into the Bedford General Infirmary, and as he showed no improvement at the end of a month Mr. Nash operated and found no fracture, dislocation, or hæmorrhage outside the cord. Some slight improvement occurred both in sensation and motion. Six weeks after the operation the patient died worn out by bed-sores and urinary complications. As no necropsy could be obtained the cause of the paralysis could not be ascertained.—Mr. Nash read a paper on Three Cases of Fracture of the Coronoid Process of the Ulna, which will be found in another column of this issue.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following have passed the Conjoint Examination for the diploma in State Medicine:—

W. A. Chapple, M.B., Ch.B, Univ. New Zealand.
H. L. Clare, M.B., B.Ch., Univ. Dub.
A. Greenwood, M.B., Ch.B., Vict. Univ.
Surgeon-Major Mulvany, L.R.C.P. & S. Edin.

A MEDICAL DEPUTY-LIEUTENANT IN IRELAND.—The Earl of Dunraven, K.P., Her Majesty's Lieutenant and Custos Rotulorum for the County of the City of Limerick, has, by commission bearing date Oct. 11th, appointed Mr. James O'Shaughnessy, M.R.C.S. Eng., L.A.H. Dub., J.P., of 7, Glentworth-street, in the City of Limerick, to be a Deputy-Lieutenant for the County of the City of Limerick.

SOCIETY OF ARTS.—The Society of Arts will commence its session (the 144th from its foundation in 1754) on the 17th inst. with an address on the Colonies, their Arts, Manufactures, and Commerce, by Major-General Sir Owen Tudor Burne, G.C.I.E., K.C.S.I., the chairman of the society's council. There will be four meetings on successive Wednesdays before Christmas, at which papers will be read by Professor James Douglas, Dr. Leonard Waldo, D.Sc., Mr. Bennett H. Brough, and Dr. Samuel Rideal, the last of whom will discuss a subject of much interest to medical men—namel, the Purification of Sewage by Bacteria.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the monthly meeting of the Fellows of the Royal College of Physicians of Ireland held on Friday, the 5th inst., the following resolutions were unanimously adopted:—1 "The College have heard with great regret of the death of Lieutenant George Duffey, and beg to express their deepest sympathy with Sir George and Lady Duffey and the other members of the family in their sad bereavement." 2 "That the President and Fellows desire to place upon record their regretful sense of the loss which has befallen the Royal College of Physicians of Ireland in the death of their distinguished colleague, the Rev. Dr. Samuel Haughton, Senior Fellow of Trinity College, Dublin; and they take this early opportunity of conveying an expression of their sympathy to the members of Dr. Haughton's family."

UNIVERSITY OF CAMBRIDGE.—Dr. A. A. Kanthack, M.A., of St. John's College, F.R.C.P. Lond., F.R.C.S. Eng., has been elected to the chair of Pathology, vacant by the death of Professor C. S. Roy.—The University Lectureship in Midwifery is vacant by the resignation of Mr. E. H. Douty, M.B. Camb. The appointment is for five years from Christmas, 1897, and the stipend is £50 a year. Candidates must send in applications and testimonials to the Vice-Chancellor by Nov. 15th.—Mr. H. K. Anderson, M.B. Camb., Demonstrator in Physiology, has been elected to a Fellowship at Caius College; and Mr. W. McDougall, M.B., house physician to St. Thomas's Hospital, to a Fellowship at St. John's College. Both gentlemen gained high distinction in the Natural Sciences Tripos.—For the examination in State Medicine in April and October of the present year seventy candidates presented themselves, and thirty-four were successful in satisfying the examiners and obtaining the University diploma in Public Health.—The degree of M.A., *honoris causâ*, was on Nov. 11th conferred on Mr. C. R. Marshall, M.B. Camb., Ch.M. Victoria, Assistant to the Downing Professor of Medicine.—Dr. A. Macalister, Mr. E. G. Browne, M.B. Camb., and Mr. F. V. Dickins, M.B. Lond., have been appointed Electors to the new Professorship of Chinese.—The Examiners in Medicine and Surgery at Cambridge University have issued a corrected plan for the Michaelmas Term Examinations. The examination in Human Anatomy and Physiology (Second Examination, Part II.) will commence on Wednesday, Dec. 15th, on which day and on Thursday, Dec. 16th, there will be written examinations, both in the morning and the afternoon. On the mornings of Friday, Dec. 17th, Saturday, Dec. 18th, Monday, Dec. 20th, and Tuesday, Dec. 21st, there will be Practical and Oral Examinations in Anatomy and Physiology in the Anatomical School and the Physiological Laboratory.

Digitized by Google

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—The Cardiff Football Club has given £90 for the purpose of establishing a scholarship to be held for three years.

SIR JOHN WILLIAMS, Bart., M.D. Lond., has been elected a member of the Council of the University College of Wales.

DORSETSHIRE COUNTY ASYLUM.—At the quarterly meeting of the Dorset County Council, held on Nov. 2nd, Lord Digby stated that during the past six months the County Asylum had made a profit on private and out-county patients of £1500, which amount had been handed over to the county treasurer.

PTOMAINE POISONING.—An inquest was held last week at Swansea upon the body of a little child who died after partaking of some roast goose, and a verdict of "Death from ptomaine poisoning the result of misadventure" was returned.

BRIDGWATER INFIRMARY.—The eighty-fourth annual general meeting of this institution was held on Nov. 4th, under the presidency of Mr. W. Holland. The annual report and the financial statement were of a satisfactory character. Mr. W. Bruce was elected President for the ensuing year.

ROYAL UNITED HOSPITAL, BATH.—The fourth annual amateur week on behalf of the Royal United Hospital was held last week at the Theatre Royal, Bath, under the direction of Dr. Lionel Weatherly, when highly successful performances were given of *The Mikado*, *A Soldier's Silence*, and *The Passport*.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The second meeting of the forty-second session was held on Nov. 5th at the Royal Kent Dispensary, Greenwich-road, Mr. W. Arbuthnot Lane, the President, being in the chair. There were sixteen members and two visitors present. Mr. C. J. Parke showed a girl, aged thirteen years, the subject of Hæmorrhagic Diathesis.—Dr. F. S. Toogood showed the following cases from the wards of the Lewisham Infirmary: (*a*) a case of Exophthalmic Goitre which had been benefited by thyroid tabloids; (*b*) a case of Spondylitis Deformans in a man; (*c*) a case of Dropped Wrist from Lead Poisoning in which there had been absolutely no recovery; and (*d*) a case of Thrombosis of the Lateral Sinus which had been operated upon with success.—Mr. C. H. Hartt exhibited a case of Molluscum Contagiosum in a woman and a case of Bronzing of the Skin resembling Addison's Disease.—Mr. Mayo Collier read notes of a fatal case of Severe Punctured Wound of the Vertebral Artery.—Dr. Ernest Clarke showed an Eye Specimen embedded in Canada Balsam.—Dr. Scholefield exhibited Diagrams of a case of Symmetrical Scotoma.—Dr. Herschell demonstrated a new arrangement of Apparatus for Washing out the Stomach.—The President, Dr. Morgan Dockrell, Dr. Scholefield, Mr. Collier, Dr. P. C. Scott, Dr. Toogood, Mr. Hartt, and Mr. Parke joined in the discussions on the various cases.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALCOCK, N. H., B.A., M.D. Dubl., has been appointed Assistant to the Professor of Physiology, Trinity College, Dublin.

ANDERSON, H. K., M.A., M.B., B.C. Camb., has been appointed to a Drosier Fellowship at Caius College, Cambridge.

ARNOLD, W., M.R.C.S., has been appointed Medical Officer for the Waltham Sanitary District of the Melton Mowbray Union.

BARCLAY-SMITH, E., M.D., has been appointed Examiner in Human Anatomy to the University of Cambridge.

BARKER, C., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Haxey Sanitary District of the Gainsborough Union.

BROWN, WM., M.B., C.M. Glasg., has been appointed Medical Officer for the Saltcoats part of the parish of Stevenston.

BURNETT, E. J., M.B., C.M. Edin., has been appointed Medical Officer and Public Vaccinator for the district of Marske, Saltburn, and Upleatham of the Guisborough Union, vice H. G. C. Collett.

CARWARDINE, T., M.B., B.S. F.R.C.S., L.R.C.P. Lond., has been appointed an Assistant Surgeon to th Bristol Infirmary.

CHAMBERLAIN, W. W., M.B., C.M. Edin., has been appointed Medical Officer of Health by the Rawden Urban District Council.

DAWSON, R., M.B. Lond., M.R.C.S., has been appointed Honorary Consulting Physician to the Brighton, Hove, and Preston Dispensary.

DINGWALL, A., M.B., M.S., has been appointed Medical Officer of Health by the Presteigne Urban District Council.

DOBBIN, E. J., L.R.C.P., Lond, M.R.C.S., has been appointed an Assistant Medical Officer for the Infirmary and the St. John's-road Workhouse of the Parish of St. Mary, Islington, vice W. B. Stanford.

FULTON, W., M.B., C.M. Glasg., has been re-appointed Parochial Medical Officer for Stevenston.

GERVIS, HARCOURT, M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Paddington Green Children's Hospital, London.

GUY, J., M.B., M.S. Glasg., has been appointed an Assistant Medical Officer for the Workhouse of the Bradford Union.

HAMPTON, T., L.R.C.P. Lond., M.R.C.S., has been appointed Resident Medical Officer to the Royal Hospital for Diseases of the Chest, City-road, London.

HARPER, H. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 5 Sanitary District of the Stow Union.

KERR, JAMES, M.A., M.D. Cantab., D.P.H., has been appointed Honorary Surgeon to the Bradford Eye and Ear Hospital, vice J. H. Bell appointed Consulting Surgeon.

MAXWELL, J. B., B.A. Cantab., M.R.C.S., L.R.C.P., has been appointed House Physician to the Royal Hospital for Diseases of the Chest.

MOORHOUSE, J. E., M.D., C.M. Edin., has been appointed a Medical Officer for the Combination Poorhouse, Stirling.

PEVERLEY, WALTER A., M.B., B.S. Durh., has been appointed Junior House Surgeon to the Ingham Infirmary and South Shields and Westoe Dispensary.

PIM, F. E. DE B., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer of Health by the Barrowford Urban District Council.

PROSSER, T. G., M.R.C.S., has been appointed Certifying Surgeon for Factories in the district of Monmouth, vice M. Poignand.

RAWLINGS, J. A., M.R.C.P. Edin., M.R.C.S., has been appointed a Consulting Physician to the Swansea Hospital.

RENTON, J. C., M.D. Edin., L.R.C.P., L.R.C.S. Edin., F.F.P.S. Glasg., has been appointed Surgeon to the Western Infirmary, Glasgow.

RICHARDSON, F. W., has been appointed Public Analyst for the Borough of Dewsbury, vice F. M. Rimmington.

SATCHELL, H. PERCY, M.B., B.S. Durh., has been appointed Surgical Casualty Officer to the General Hospital, Birmingham.

SAVAGE, W. G., L.R.C.P. Lond., M.R.C.S., has been appointed a Resident Medical Officer to the Sussex County Hospital, Brighton.

STOCKMAN, R., M.D. Edin., F.R.C.P. Edin., F.R.S.E., has been appointed a Physician to the Western Infirmary, Glasgow.

TRIPP, C. L. H., M.R.C.S., has been appointed a Medical Officer for the Dawlish District of the Newton Abbot Union.

WADE, R., M.R.C.S., has been appointed Medical Officer of Health by the Highbridge Urban District Council.

WATSON, D. C., M.B., C.M. Edin., has been appointed a non-resident Clinical Clerk to the Observation Ward, Royal Infirmary, Edinburgh.

WHITE, ARTHUR HAMILTON, L.R.C.P. and S. Irel., has been appointed Professor of Pathology at the Royal College of Surgeons in Ireland.

WILSON, G. R., M.B., C.M. Edin., has been appointed Medical Officer for the No. 1 Sanitary District of the Blackburn Union, vice T. W. Gregson.

WOODHOUSE, CECIL, B.A., M.B., B.C., has been appointed House Physician to the Paddington Green Children's Hospital, London.

WOODWARD, A., L.R.C.P. Lond, M.R.C.S., has been appointed a House Surgeon to the Metropolitan Hospital.

WILLIAMS, G. E., L.S.A., has been appointed a District Medical Officer for the Carnarvon Union.

WITHAM, H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Kirton Sanitary District of the Boston Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BLACKFRIARS PROVIDENT DISPENSARY, London.—Lady Medical Officer. Salary equal to £120. Apply to the Secretary, Miss Fowler, 45, Nelson-square, S.E.

BRADFORD ROYAL INFIRMARY.—Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.

BRISTOL GENERAL HOSPITAL.—House Surgeon for three years. Salary £120 per annum. Board, residence, &c., provided in the house.

Births, Marriages, and Deaths.

BIRTHS.

BAKER.—On Nov. 6th, at Bedford-square, W.C., the wife of J. H. Baker, M.D., of a son.

BEEVOR.—On Nov. 8th, at Harley-street, W., the wife of Charles E. Beevor, M.D., F.R.C.P., of a daughter.

MACLENNAN.—On Nov. 6th, at Lerwick, Shetland, the wife of A. A. Maclennan, M.B. Aberd., of a daughter.

PARRY.—On Nov. 6th, at Youlgreave, Derbyshire, the wife of T. Wilson Parry, M.A., M.B. Cantab., of a daughter.

MARRIAGES.

ARTHUR—ROSS.—On Nov. 2nd, at Abbotsville, Cults, Aberdeen, Alexander T. Arthur, M.B. Aberd., to Margaret King, daughter of Rev. Adam Ross, M.A., Senior Minister of the Free Church, Rattray, Blairgowrie.

DOWNES—AKERS.—On Nov. 4th, at St. Peter's Church, East Blatchington, Seaford, by the Rev. A. J. Richardson, M.A., Godkin Downes, M.R.C.S., L.R.C.P., L.S.A., of Keston, 47, Beckenham-road, Beckenham, Kent, to Mary Ethelreda, widow of the late Charles Akers, Esq., 1, Clapton-common, N.E., and 11, Abchurch-lane, E.C., and youngest daughter of Henry Brown, Esq., and the late Mrs. Brown of Pendilo, 73, Cazenove-road, Stamford-hill, N. No cards.

O'BRIEN—SHAW.—On Sept. 28th, at St. David's Cathedral, Hobart, Tasmania, Philip Kennedy O'Brien, L.R.C.P. Lond., M.R.C.S. Eng., son of the late W. Creagh O'Brien, M.D., &c., of Maidstone, to Margaret Beryl Fenton, elder daughter of the late James Fenton Shaw, of Swansea, Tasmania.

RAW—STRONG.—On Nov. 6th, at the Pro-Cathedral, Liverpool, by the Rev. George Raw, M.A., brother of the bridegroom, Nathan Raw, M.D., B.S., F.R.C.S., of Liverpool, to Annie Louisa, fourth daughter of the late Charles East Strong, Solicitor, of Union-court, Old Broad-street, and Lordship-park, London.

DEATHS.

CARTER.—On Nov. 4th, at 45, Great Cumberland-place, W., suddenly, Hannah, the wife of Charles H. Carter, M.D.

HAZELL.—On Oct. 9th, at 1, Bouquet street, Cape Town, South Africa, Robert William Hazell, M.R.C.S., L.R.C.P., L.S.A., aged 49 years.

SCOTT.—On Nov. 8th, at Cramond House, Sandwich, John Scott, M.D., aged 63 years. Friends will kindly accept this intimation.

WETHERED.—On Nov. 4th, at Gratnar, near Moreton-Hampstead, Devon, Charles Wethered, M.R.C.S., Hon. Assoc. Royal Inst. Brit. Architects, late of West Grange, Stroud, Gloucestershire, aged 70 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

WANTED A REMEDY IN SEVERE LUMBAGO.

L.R.C.P. writes that he will be grateful to his brother practitioners for advice with a view to relief from severe lumbago of four months' standing. His age is thirty-nine years, and he has tried colchicum, potassium, salicylates, guaiacum, sodium, and sulphur and hot-water bags and mustard leaves. He has tried all kind of aperients. He wears flannel and eats little meat. He cannot take iodide of potassium though he is gouty.

M. K. Q. C. P. I.—It would be wiser to make a change.

AN ORIGINAL REMEDY FOR HEADACHE IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—On the evening of Oct. 19th I was called to visit a Roumanian boy, six years old, suffering from typhoid fever. I found him *in extremis*, almost pulseless. The child's head was completely wrapped over with a large white sheet, and as I looked at it this enormous white envelope seemed to be on the move. Whilst I was surveying this covering there crept from under it a small frog which quietly sat over the child's left eye. It seemed quite content. I immediately called the mother's attention to it, and requested her to take the beast away, thinking that it had crept there as an intruder. "Oh, no!" said the old lady, "a doctor recommended that a lot of them should be kept to the head to keep it cool." Seeing the head covering still on the move I raised it for curiosity, and in a second out jumped about twenty other frogs, and away they hopped in all directions. I have often heard the expression "as cold as a frog," but this was the first time I had seen a frog applied as a head-cooler.

I am, Sirs, yours faithfully,

A. IRWIN BOLTON, M.B. Dub.

Constanta, Roumania, Oct. 26th, 1897.

"THE CHRISTIAN."

THIS stupid book has received very severe handling in the press, but to our mind no paper has treated it more fitly than our bright little contemporary, the *Guyoscope*. The reviewer in the *Guyoscope* made no parade of wide literary reading; he did not discuss with the author the ethics of the sensational novel or the trend of modern religious thought; he simply "rotted" Mr. Hall Caine for having written absurdly, mendaciously, and (which is worse) unfairly about hospitals, house-surgeons, and nurses. The *Guyoscope* returns to the attack in the current issue, and in view of the persistent manner in which "The Christian" has been puffed we see nothing malevolent in a little persistence on the other side. In a short article called "Hospital Hoppings," the scene of the famous ball at St. Bartimœus is happily ridiculed. At this ball, it will be remembered, the President of the College of Surgeons, a fashionable lordling, the students and the nurses abandoned themselves to the dance together. The students pulled down the nurses' hair, and a gentleman in a Government Office accompanied the heroine (a probationer) back to her hospital in the early dawn. To this restrained and accurate picture of hospital life the *Guyoscope* adds a touch or two of local colour deserving of quotation:—

"HOSPITAL HOPPINGS."

"Last Tuesday the first students' ball of the season took place in the operating theatre of St. Bartimœus' Hospital. ..... The arrangements generally reflected great credit on the members of the dance committee, who, by the way, were distinguished by wearing Murphy's buttonholes in their coats. ..... The floor had been carefully scrubbed with soft soap and lysol, and would have made an admirable dancing surface had there been room to dance. As it was the majority of the guests preferred to take advantage of the magnificent promenade afforded by the spacious corridors of the hospital. ..... The proceedings opened with a solo clog-dance on the operating table by Sir William McCormac, who was attired in mackintosh and sterilised overall. Next, in response to vociferous appeals, the matron of the hospital obliged with a serpentine dance, all first year's students having been previously anæsthetised. After these two superb displays of Terpsichorean skill, a general move was made for the supper room, a delightfully airy apartment, used on more prosaic occasions as a dissecting-room. Boyish students might be seen pledging their laughing-eyed partners in foaming beakers of hyd. perchlor. (1 in 2000, 1897), while their staider elders fortified themselves with modest injections of brandy and strychnine. We can personally testify to the exhilarating qualities of the Formalin Cup, which was much appreciated by those privileged to partake. If a criticism can be permitted us, we venture to think that the conduct of the surgical instrument keeper in boiling the spoons between every course was somewhat unnecessary and certainly inconvenient."

We think this excellent fooling, and ridicule is what pretentious rubbish like "The Christian" wants.

E. M. G. is thanked for the communication. We doubt if public exposure does much good, but we are always glad to learn of these people that we may be prepared to advise our correspondents concerning them.

IMMOBILITY IN FRACTURE OF THE LOWER THIRD OF THE FEMUR.

To the Editors of THE LANCET.

SIRS,—Some years ago when resident pupil at a general infirmary I, in the absence of the house surgeon, admitted a man who had sustained a compound fracture of the left tibia and a simple fracture of the right femur in its lower third. The lower fragment was displaced upward and backward, requiring some force to reduce the deformity. When the visiting surgeon and the house surgeon came I described the injuries. They both declared that there was no fracture of the femur and desired me to examine it again. I then failed to get any mobility or crepitus. I was of course gravely reprimanded for having committed such an error. In a few days the man died, and to justify myself I took the senior surgeon to the mortuary and in his presence exposed the bone. There was the fracture just above the condyles. The old gentleman observed: "Ah! just so, sir, very satisfactory, but at any rate you had no business to contradict me." The other night I was called to the station to see a man who had been severely tumbled about amongst some goods trucks. I examined him carefully, as well as one could in a dark shed by the light of railway lamps, looking out for a fractured femur, but could not get evidence of it. He was sent to the neighbouring hospital and after being placed in bed and relaxation of his muscles had taken place a fracture of the lower third of the femur was easily made out. In the first case, had the patient not died he would have kept his bed for six weeks or so, thus allowing time for the consolidation of the fractured femur while the opposite tibia was receiving attention, and I should have remained under the stigma of a gross error in diagnosis.—I am, Sirs, yours faithfully,

J. G. CARRUTHERS, M.R.C.P. Edin., &c.,

Selhurst-road, S.E., Nov. 9th, 1897. Divisional Surgeon.

A NEW FLOWER-POT COVER AND LIFTER.

Mr. H. ADEANE, of 51, Edbrooke-road, St. Peter's-park, W., has introduced a new ornamental flower-pot cover, lifter, drainer, and vase guard which will be a convenience to those who keep flowers indoors for decorative purposes. The usual practice is to place the coarse earthenware flower-pot inside an ornamental vase an inch deeper than the pot, so that the latter is concealed, a system which renders cleaning difficult, because there is seldom room for the fingers to pass between the pot and the vase. The consequence is that decaying vegetable matter accumulates inside the vase, and is apt to become offensive and unwholesome through being kept damp by the water used for the plant. Mr. Adeane's invention is intended to remedy this defect by enabling the flower-pots to be easily kept clean.

A Country Cousin.—The Jubilee medals are awarded for no "special service." They are a Royal recognition of general service, personal or public, rendered to the Crown. The Victoria Cross is awarded to persons displaying conspicuous bravery ("For Valour") on the field of battle. It is obvious that these are seldom civilians, but one of the awards announced in this weeks' *Gazette* conferred a decoration on Lord Fincastle, a soldier whose presence, however, on the scenes of war was due to other than military reasons.

"A POINT IN THE WORKING OF THE 'INFECTIOUS DISEASES NOTIFICATION ACT.'"

To the Editors of THE LANCET.

SIRS,—Fearing my letter of Oct. 4th (which you so kindly answered in THE LANCET of Oct. 23rd) was not very clearly expressed, I am again troubling you to answer "Yes" or "No" to the following question:—Has the port medical officer any jurisdiction over a ship upon which after it has been declared by the sanitary inspector "all well" on board and the captain and crew have been ashore infectious disease breaks out, we will say for argument, twenty-four hours after? The nearest general practitioner is called in and removes the patient to the hospital. Does the general pratitioner act rightly, or should he send a report to the medical officer of the port or the medical officer of health?

I am, Sirs, yours faithfully,

Fowey, Cornwall, Oct. 29th, 1897. W. H. BOGER.

*** Our correspondent speaks of a question, but there appear to be two questions. 1. The port medical officer has jurisdiction over every vessel within his district, and over any case of infectious disease occurring on any such vessel at any time. (See Duties of Port Medical Officers under Order of the Local Government Board, July, 1883). 2. If notification has been adopted both by the port sanitary authority and by the district council adjacent to the port the occurrence of a case of infectious disease on a ship must be notified to the port medical officer of health, so that he may disinfect the ship, &c., and when the case is removed ashore a notification must be sent to the authority on shore.—ED. L.

POND'S ARCH SUPPORT FOR FLAT-FOOT.

THE natural arch of the foot is supported in part by the ligaments of the sole and in part by muscles and tendons. When these structures are no longer able to hold up the arch flat-foot is produced. When it is possible to restore the healthy tone of these natural supports of the arch so that they may take up again the function which they have resigned no artificial support is desirable; but in very many cases this is not possible, and then it is necessary to provide a mechanical support for the arch to relieve the pain and discomfort to which the flat-foot gives rise. We have examined and made use of Pond's arch support which was sent for our inspection. It consists of a "sock" containing a piece of steel fitted to the under-surface of the whole arch of the foot. It affords a wide-spread comfortable support, and is very suitable for the cases we have indicated above. It may be obtained from Mr. J. Pond, 23, Castle Meadow, Norwich; or from the London Shoe Company, 123, Queen Victoria-street, E.C.

Dr. T. Granville Hockridge.—We have only one side of the case before us. From the facts submitted to us we think it would have been polite if B had asked A to be present at the post-mortem examination, but we do not think A should take offence at the omission.

A PHYSICAL SIGN IN TYPHOID FEVER.

To the Editors of THE LANCET.

SIRS,—I have noticed in cases of typhoid fever a yellow discolouration of the palms of the hands which is usually noticeable in the second week and gets darker till the crisis, then gradually disappears as the temperature regains the normal. Is this a definite symptom? It is not mentioned in books. The Maidstone epidemic is a good opportunity for confirming this if it should be the case.

I am, Sirs, yours faithfully,

Nov. 3rd, 1897. J. W. S.

MENTAL DISTURBANCE AFTER GYNÆCOLOGICAL OPERATIONS.

THE American *Medical and Surgical Reporter* publishes a paper in which Dr. John A. Lyons gives an account of two cases where plastic operations were followed by mental disturbance. The first patient was thirty-four years of age and the mother of three children, the last one being two and a half years old. She seemed very much above the average in intelligence, of exceedingly good physique, and not naturally of a nervous temperament. She suffered from leucorrhœa and dysmenorrhœa; the uterus was enlarged, "evidently sub-involuted and endometric, because of an exceedingly large bilateral laceration of the cervix, the os admitting an index finger with but little force, but with considerable pain." The operation consisted in thorough curettage of the uterine canal and trachelorrhaphy. The uterus was well packed with iodoform gauze, which was removed at the end of forty-eight hours. The sutures were removed from the cervix eight days later, as perfect primary union had taken place. After the operation her mental faculties were impaired, she was often oblivious of her surroundings, and her children disturbed her so much that they had not unfrequently to be removed from her presence. This state of affairs continued for about four months, when she was seized with acute mania in consequence of the death of a brother, but within two months from this date she entirely recovered, not a trace of dementia being left. The second patient was thirty-one years of age; she had two children, aged ten and twelve years respectively, and had not been pregnant since the birth ten years previously. She suffered from a complete perineal laceration extending up the rectum almost to the vaginal vault, so that she had incontinence of gas and fæces, but a plastic operation was performed with such success that she obtained perfect control of the rectum. In less than two months, however, her mind was completely unbalanced; she became morose, gloomy, indifferent to her family, and sleepless. "When upon the street she imagined all men she happened to see were following her with evil intent, so that it became necessary to have an escort with her while taking her morning and evening walks." After having continued some five months these mental symptoms disappeared and the patient has since been delivered of an unusually large child without experiencing any perineal injury.

WHAT IS THE MEDICAL MAN TO DO?

To the Editors of THE LANCET.

SIRS,—I should esteem it a favour if you would give me your opinion as to the duty of a medical man under the following circumstances:—A young man consulted me at my house and upon examination I found him to be desquamating freely; this together with his history led me to diagnose scarlet fever, and I ordered the patient home and notified accordingly. I have since ascertained that I have infringed the 126th section of the Public Health Act and thereby made myself liable to a penalty of £5. Now, as general practitioners must be frequently doing the same thing—viz., "exposing or causing to be exposed, a person suffering from infectious disease" you will be conferring a favour upon others besides myself by advising us how to act.

I am, Sirs, yours faithfully,

Oct. 8th, 1897. INQUIRER.

WANTED, A HOME FOR A FEMALE DIPSOMANIAC.

To the Editors of THE LANCET.

SIRS,—Can any of your readers refer me through your columns to an institution or home for female dipsomaniacs charging not more than 30s. weekly inclusive?—I am, Sirs, yours faithfully,

Nov. 8th, 1897. M.R.C.S.

During the week marked copies of the following newspapers have been received: *Hull Daily News, Sun, Stirling Observer, Salisbury Journal, Yorkshire Herald, Newcastle Journal, Times of India, Pioneer Mail, New York Herald, Wiltshire County Mirror, Evesham Journal, Thanet Guardian, Architect, Liverpool Daily Post, Cambs Times, Manchester Guardian, Kidderminster Shuttle, Lincolnshire Echo, Grimsby Mail, Builder, Leeds Mercury, Scotsman, Hereford Times, Elgin Courant, Luton Reporter, Sussex Express, Walsall Advertiser, Bristol Mercury, Dundee Advertiser, North British Daily Mail, Bradford Observer, Somerset County Herald, Birmingham Gazette, Isle of Wight Herald, Bridgwater Independent, Yorkshire Post, Hinckley Times, East Anglian Times, Eastern Press, Burnley Express, Brighton Gazette, Sanitary Record, Wolverhampton Chronicle, Bath Chronicle, Scottish Guardian, City Press, Reading Mercury, Hertfordshire Mercury, Lincolnshire Echo, Mining Journal, Local Government Chronicle, Worthing Gazette, Weekly Free Press and Aberdeen Herald, Lincoln Gazette, Surrey Advertiser, People's Journal, Inverness Courier, Perth Constitutional, La Gazette de France, Leicester Post, Loughborough Monitor, Banffshire Journal, Liverpool Courier, Family Herald and Weekly Star (Montreal), West Middlesex Herald, North Wilts Guardian, Manx Sun, East Grinstead Observer, &c., &c.*

"APENTA"

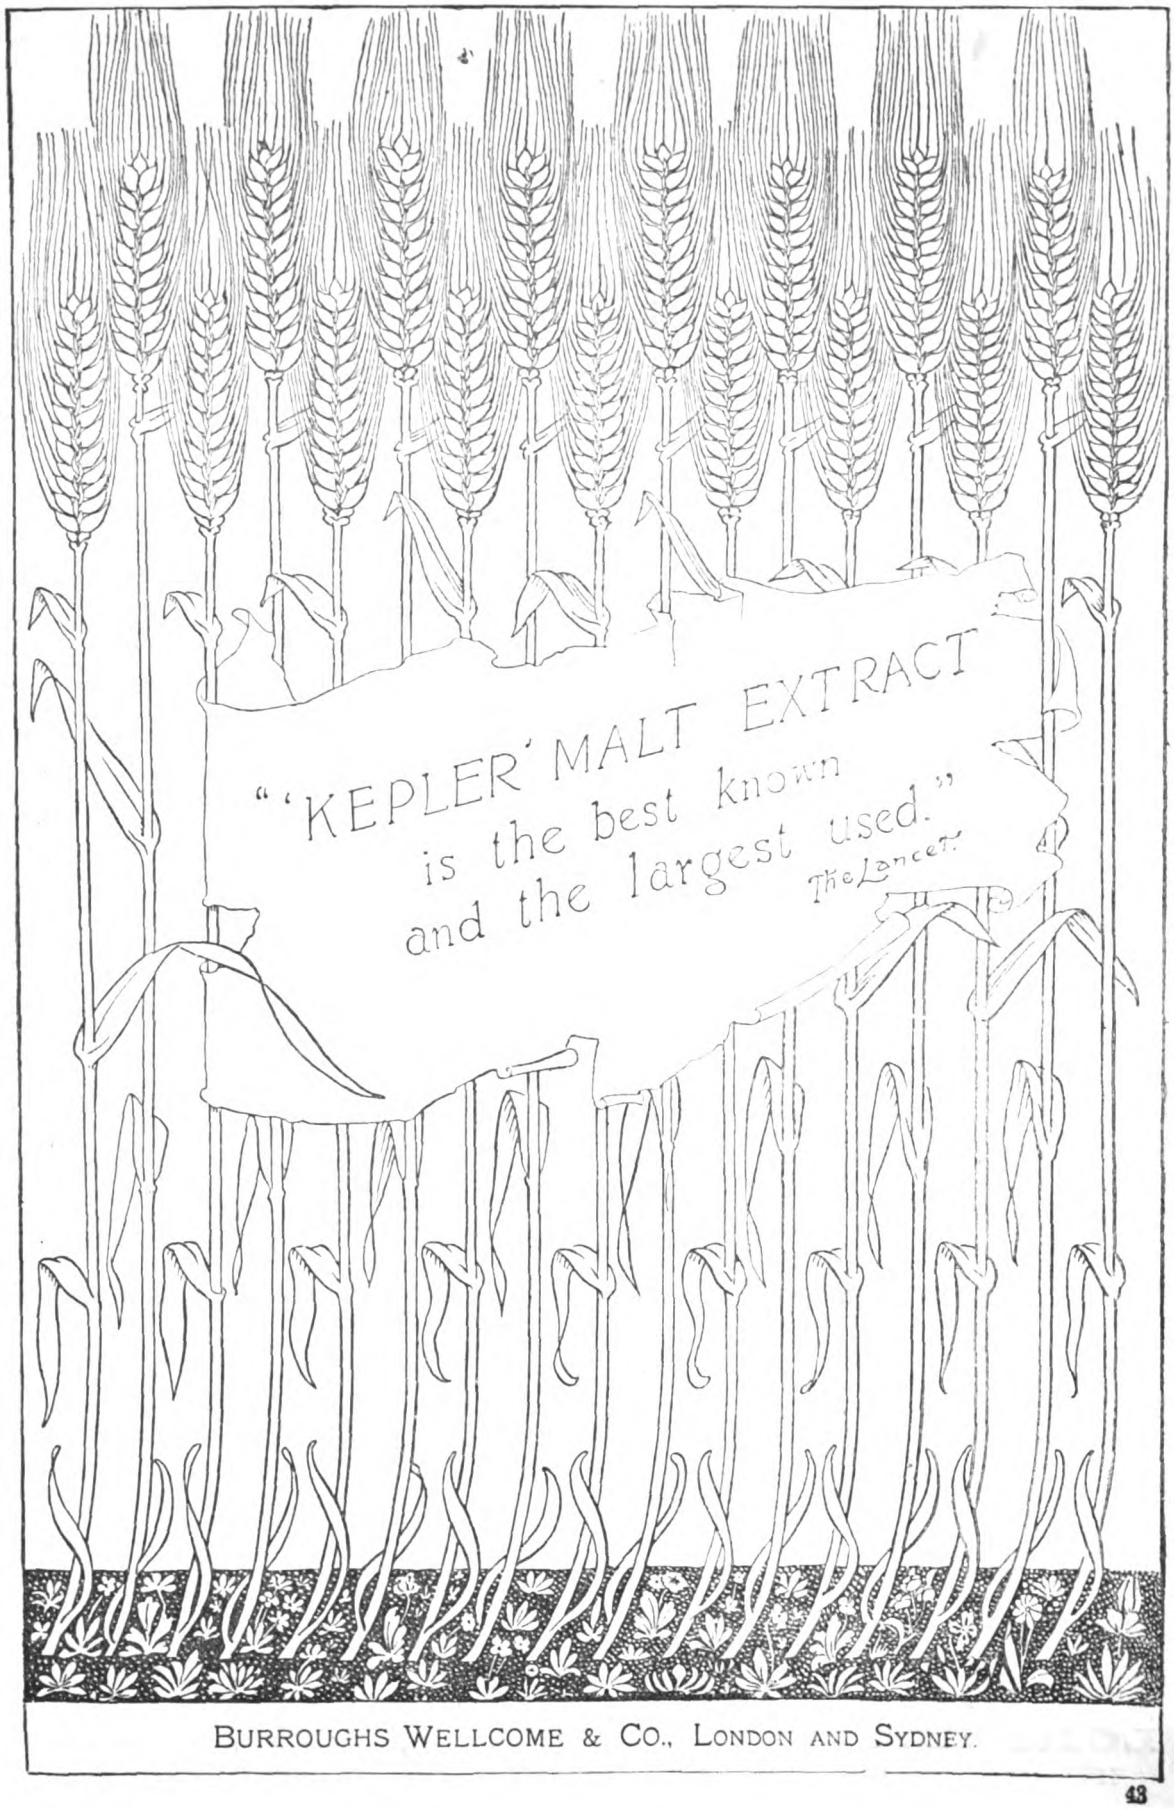
THE BEST NATURAL APERIENT WATER.

Bottled at the Springs, Buda Pest, Hungary, under Eminent Scientific Supervision.

CONCLUSIONS from Clinical Observations on the action and value of APENTA WATER in Obstinate Constipation by Professor W. S. BOGOSLOWSKY, Director of the Pharmacological Institute of the Moscow University, &c., &c :—

"Systematic treatment with APENTA Water is especially indicated for Constipation produced by Atony of the Bowels, and Apenta possesses without doubt this advantage over other aperients, that its use does not give rise to subsequent constipation.

"By suitable doses of this water the bowels act freely and considerable quantities of bile are evacuated. The action of APENTA Water is more gentle than that of the bitter waters most known with us because it contains less calcium sulphate and no magnesium chloride. It is probably due to this circumstance that the crampy pains generally observed when aperients are employed are entirely absent in the case of APENTA.



"The efficiency of APENTA as a remedy for the systematic treatment of Obesity in general is clinically established."

A Translation of the Report of Professor W. S. Bogoslowsky, read at the Meeting of the Society for the Preservation of Public Health, Moscow, will be forwarded on application to

UP-TO-DATE PRODUCTS.

AWARDED 3 GOLD MEDALS 1884 EXCELLENCE of QUALITY & MANUFACTURE.

COCA WINE (Lorimer).

A Pure Wine with accurate admixture of a certain proportion of the stimulant and recuperant principles found in the picked leaves of Erythroxylon Coca. The virtues of this plant were made known by Sir Robert Christison, F.R.S., and have since increased in repute among the Profession. **Indicated in Dyspepsia, Gastralgia, Sea-Sickness, Alcoholism, Neurasthenia, Influenza, Asthma, Chorea, Morphinism, Convalescence, Melancholia, &c.**

Price 29/- per Doz.

The MEDICAL ANNUAL, 1892, page 587, affirms:— "That Lorimer's Coca Wine compares very favourably with other samples, and contains all the stimulating and tonic properties of the Coca dissolved in a generous and palatable wine."

FELS'S GERMICIDE SOAP.

A pure, unadulterated Emollient for the Skin, strongly **microbicidal**, antiseptic, and deodorant, owing to the admixture in good proportions of Corrosive Sublimate, Eucalyptus, Sal Alembroth, &c., fully approved by physicians as the most serviceable bactericides known. Equally valuable as a toilet article and medicinal preparation.

"This soap is a very efficient antiseptic."

Price 1/- per Tablet. —MEDICAL ANNUAL, 1895.

ANTIRRHEON (Lorimer).

This contains P. Gallæ, Acid Carbolic c. Ext. Hamamelidis. This, with accompanying Cachets of useful aperients, forms an elegant therapeutic method of overcoming such painful and distressing diseases as Hæmorrhoids, Fissure, Rhagades Ani, Proctitis, Peri-proctitis, Ischio-rectal Thickening with Threatened Abscess. The preparation is *de facto* the prescription of an eminent specialist. **Price 1/1½ per box.**

OL. IODISATUM (Lorimer). Patented.

A most active Iodine Embrocation Liniment. Is always effectual. Does not discolour the skin. Is readily absorbed, and does not irritate the most hypersensitive skin. Is regarded by eminent physicians as far superior to all other Iodine Liniments, &c., for external application. Prescribed with the best results as an Embrocation in **Coughs, Colds, Bronchitis, Influenzal and Catarrhal Conditions, Rachitis, Chronic Lymphadenitis, Chronic Rheumatism, Articular Swellings, Bronchocele, &c. Price per bottle, 1/1½, 2/9, and 4/6 each. In bulk, 6/- lb.**

CAPSULÆ RASPAIL.

The most scientific and pleasant form in which to administer nauseous or irritating medicines. They keep perfectly; easily swallowed; dosage accurate; no after-taste. **EASTON SYRUP CAPSULES.**—An active and reliable tonic for all complaints marked by Debility and Depression, Neurasthenia, Paralysis, Convalescence after Acute Affections. &c. **Price 10/6 per doz. tins; 21/- per 1000. CASCARA CAPSULES.**—For Chronic Constipation, Delicate Women and Children. A perfect laxative. **Price 7/6 per doz. tins; 15/- per 1000. OL. SANTAL FLAV. CAPSULES.**—Can be taken without the least discomfort. Largely prescribed in Gonorrhœa, Blennorrhagia, &c. **Price 12/- per doz. tins; or per 1000, 35/-.**

SANOLINUM. (S. gr. 860.)

A pure Oil from Petroleum. Free from colour, odour, and taste. A perfect solvent for Camphor, Menthol, Thymol, Salol, &c. Well adapted for use with every Atomizer. **1 lb., 1/6; 4-oz. bots., 6/- doz.**

SYRUP. HYPOPHOSPHITUM CO. (Lorimer).

A powerful tonic, alterative, and reconstituent to Blood, Muscle, Bone, and Brain One of the best known and most approved remedies in **Tuberculosis, Chronic Bronchitis, Asthma, Anæmia, Chlorosis, Convalescence after Fevers and Acute Diseases, Malnutrition and Emaciation, Constipation. Dyspepsia, Alcoholism, Morphinism, Uterine and Ovarian Affections, Neurasthenia, Neuralgia, Hysteria, Hypochondria, Epilepsy, Chorea, Rachitis, &c. Price, unstamped, ½ lb., 1/-. 1-lb., 3/- Doz.**

CREMOR ZINCO-BISMUTHI (Lorimer).

An emollient Cream of striking therapeutic value for local application in Cutaneous Disorders. It is an emulsion of Boric Acid, Zinc Oxide, and Bismuth with pure Vaseline. It has proved on clinical trial to afford great freedom from pain and irritation in Erysipelas, Burns, Scalds, Dermatitis, Eczema, Pruritus, Acne, &c. **Action:** The evaporation of contained H_2O lowers temperature of skin rapidly. **Price 2/- per bottle.**

PYRIDIN ETHYL-PHOSPHINATE.

The value of Pyridin was fully established in Lung Complaints by Professor Sée (Paris), but, the remedy proving nauseating and irritating to a degree, by experiment this new and definite chemical compound was discovered, and the following results noted in the treatment of phthisis—viz: Cough much soothed; abolition of night sweats; increase in both appetite and weight. It is pleasant to take, never causes objectionable symptoms, and never fails to benefit the sufferer from Phthisis. Bronchitis, Pneumonia, Pertussis, Asthma, &c. **Price, in 1 lb. bottles, 5/- each.**

PIL. No. 5 a (Lorimer).

℞ Ext. Damianæ, gr. i.; Ext. Cocæ, gr. ½; Ext. Nucis Vomicæ, gr. ¼; Phosphori, gr. 1-100. May be prescribed—℞ Pil. 5a Lorimer.

A valuable combination of powerful stimulant drugs. Damiana is recognised as a stimulant **Aphrodisiac,** Coca increases muscular and cardiac power, and stimulates the digestive, peristaltic, and other functional processes. **Phosphorus**—the chief tonic and reparative to the central nervous system. **Price per gross 2/5.**

PARAHYDROPIN (Lorimer).

℞ Theobromin, Scoparin, &c.

A standard and active Compound Diuretic. Its action is rapid, definite, and regular. A Scientific Substitute for Toxic Digitalis, irritating and uncertain Caffeine and its Salts.

S—— R——, M.D., F.R.S., "Handbook of Therapeutics," 1897, page 595, states that Theobromine is a powerful diuretic. ..... Is more prolonged in its effects and does not cause sleeplessness as Caffeine does. ..... Therefore, Theobromine has the advantage over Caffeine as a diuretic."

Therapeutic Indications: Ascites, Anasarca, Œdema associated with Cardiac, Hepatic, and Renal Disease.

LOTIO HAMAMELIDIS CO. (Lorimer).

A useful combination of Sedative and Antiseptic Drugs in solution. This Lotion has been largely prescribed by Surgeons and Practitioners generally as an external application in cases of **Acute Inflammation, Incised or Lacerated Wounds, Burns, Scalds, Fernio, Condylomata, Erysipelas,** by means of a pad of St. John's Lint; as an Embrocation in **Rheumatism, Lumbago, Sciatica, Neuralgia,** &c., with the most beneficial effects. **Price 1/1½ and 2/9 per bottle.**

Supplementary Croonian Lecture

ON

POINTS CONNECTED WITH THE PATHOLOGY AND TREATMENT OF DIABETES.

Delivered before the Royal College of Physicians of London on Nov. 13th, 1897,

BY F. W. PAVY, M.D LOND., LL.D, F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

MR PRESIDENT, COLLEAGUES, AND GENTLEMEN,—I appear before you to-day to draw your attention to points connected with the pathology and treatment of diabetes. They constitute the outcome of the study which formed the basis of the Croonian Lectures delivered by me in 1894 and of the study I have since conducted. Disease is a deviation from health, and for its proper comprehension we require to have a knowledge of the conditions belonging to health. It is just this in the case of diabetes that it has been difficult to obtain and the complaint has stood as one of the most inscrutable of diseases. The question first presented for solution is, How does carbohydrate normally become disposed of in the system? Next follows the question, What is it that gives rise to its unnatural escape with the urine?

Briefly stated, diabetes may be said to consist of a malapplication of the carbohydrate principles of food. Common observation teaches us that when the various forms of carbohydrate matter are taken by a healthy person with the food they become lost sight of and contribute to the benefit of the system. The system has the power of placing them in a position to be susceptible of utilisation, and they thus disappear from view with resultant good. In the case of the diabetic, however, the carbohydrate matter that is ingested fails to undergo proper application, and passes, instead, as sugar through the system to the urine, with which it is discharged as waste material. This is the plain statement of fact regarding the difference between health and diabetes, and what is wanted is a right understanding of the details concerned.

It has been hitherto assumed, without any positive evidence as a basis, that the carbohydrates undergo oxidation in a direct manner in the system. Liebig placed them in his group of calorifacient food principles. In his time physiology and chemistry were not sufficiently advanced to permit of carbohydrate matter being followed after being taken as food so as to obtain information of the phenomena occurring. The first step in this direction was the renowned work of Bernard. Bernard, accepting the view that the carbohydrates are destined for the purpose of oxidation within the system, enunciated the doctrine that the liver is endowed with a glycogenic function which provides a supply of sugar to be conveyed to the tissues for oxidation when carbohydrate matter is lacking in the food. I need not give attention here to the faulty groundwork upon which the glycogenic doctrine was raised. This matter has in times past been amply dealt with. Notwithstanding, however, that it is recognised that the experimental groundwork is fallacious the doctrine has become so firmly implanted in the mind as to render effacement difficult. Apart from other considerations, what it implies affords its condemnation. In order that sugar may reach the tissues for oxidation it must enter the general circulation. Now it happens that the stream of blood alleged to convey sugar to the tissues for destruction in part goes to the kidney. It was formerly taught that the capacity existed of tolerating a certain amount of sugar in the blood without its passing off with the urine, and this tolerating capacity was asserted to have been found in the dog to stand good for a proportion of 2·50 per 1000; in other words, when sugar amounted to 2·50 per 1000 in the blood sugar escaped with the urine, but not when a less proportion existed.

At that time neither for blood nor for urine were the analytical methods for the recognition and determination of sugar in the satisfactory position in which they stand now. Modern physiologists are agreed that the amount of sugar normally present in blood is about, or a little under, 1 per 1000; and in association with this it can be definitely stated that sugar passes into the urine. It can also be definitely stated that in association with 2·5 per 1000 of sugar in the blood such an amount passes into the urine as to give it a pronounced saccharine character. The question of the presence of sugar in normal urine long stood, or was considered to stand, as a debatable point. The discussion on the subject that took place in the pages of THE LANCET a few years back, in which I took part, will probably be remembered. The method formerly adopted for separating the sugar from the urine and obtaining it in sufficient quantity for its satisfactory identification was by precipitation with lead acetate and ammonia. Operating upon the product yielded by this process I obtained information which left no doubt in my own mind that sugar constitutes an ingredient of healthy urine. More recently Baisch and others have operated with benzoyl-chloride. By this reagent sugar may be precipitated and can afterwards be recovered in a pure form. From the evidence that has been obtained the matter may be considered to have been thoroughly set at rest. Not only, indeed, can it be said that sugar has been found, but likewise that its nature has been defined.

The point to which we are led is that no tolerating capacity exists against elimination by the kidney of sugar present in the blood. As it is present so it escapes, and the urine thus becomes a delicate indicator of the condition of the blood. By experiment it can be shown that sugar introduced into the circulation is at once revealed by the urine. I have found that even as small a quantity as a quarter of a gramme per kilo. body weight—that is, a four-thousandth of the weight of the animal—intravenously injected has given evidence of influence upon the urine. Where larger quantities are used a more or less pronounced elimination occurs, and the blood even an hour afterwards has not regained its normal constitution, but still retains a surplus of sugar. This tells against the assumed destruction in the systemic capillaries being the natural mode of application of sugar in the animal economy. It is sufficiently evident that the kidneys constitute the channel through which the sugar permitted to reach the circulation in diabetes is discharged from the system. The action of the kidney in relation to sugar is not different in health from that in diabetes. The only difference is one of degree determined by the difference in the amount of sugar existing in the blood. It is not surprising that in former times healthy urine was regarded as being free from sugar. The quantity is too minute for the chemical methods then at command to reveal. With the improved methods of the present day the sugar which is present in healthy urine, and is derived from the small amount naturally existing in the blood, is readily susceptible of demonstration.

From the considerations that I have mentioned it is permissible to look to the urine for the supply of knowledge regarding the entry of sugar into the blood of the general circulation, and to reason as follows in relation to the glycogenic doctrine. Under natural circumstances the blood contains a certain small amount of sugar which may be considered as constitutionally belonging to it, just as is noticeable with the other constituents of the body. Physiologists are agreed that the amount of sugar in the blood is not altered by the amount of carbohydrate ingested. Within ordinary limits both the blood and the urine remain uninfluenced by the character of the food with respect to carbohydrate. It matters not whether the comparatively insignificant amount of carbohydrate existing in an animal diet or the large amount contained in many articles of food from the vegetable kingdom be ingested the result is the same. But could this be the case if the ingested carbohydrate had to be conveyed as sugar through the general circulation to the systemic capillaries to be there disposed of? It would mean that, notwithstanding the demonstrable fact that whilst the introduction of an exceedingly small amount of sugar into the circulation gets revealed by the urine, a surpassingly large amount can reach it from the food without evidence being afforded of its doing so. The circumstances are such that whatever presumably passes to the tissues for destruction would equally pass to the kidney for elimination. If the kidneys were placed on the other side of the systemic capillaries there might be destruction without elimination. But it is the same stream that goes to the systemic and to the renal capillaries, and for the teaching to hold good it would have to be assumed that destruction could proceed and elimination remain in abeyance. By the ingested carbohydrate being temporarily stopped

Digitized by Google

by the liver and stored as glycogen the difficulty is not removed. Within a given time the transit would have to be made, and the amount transported under a free carbohydrate diet would be infinitely greater than could be derived in any way from animal food, and yet it escapes being revealed by the urine. What the quantity is that would have to pass may be judged of by the difference in the amount of sugar eliminated by a diabetic patient partaking freely of carbohydrate materials on the one hand and upon animal food only on the other. Everyone knows the immense difference existing, but I may mention in illustration the figures drawn from a case in which many years ago I specially studied the effect of different kinds of food on the elimination of sugar. The sugar voided during a twenty-four hours' period on a diet exclusively of animal food stood at thirty-seven grammes, whilst for a similar period with a diet containing a plentiful supply of carbohydrate material it reached 685 grammes. This gives an idea of the amount of sugar that would have to traverse the circulation if the carbohydrate matter of our food had to be conveyed as sugar to the tissues for destruction. And yet in the healthy state the urine escapes without any effect being produced upon it. If in reality the functional transit did take place it could not fail to be rendered conspicuously evident by the urine. The transit, indeed, is just what belongs to diabetes, and I submit that this consideration is fatal to the glycogenic doctrine. For freedom from diabetes, carbohydrate matter must be prevented reaching the general circulation as sugar instead of being thrown into it as such for conveyance to the tissues for destruction. And now the problem that presents itself for our consideration is, In what way does the carbohydrate matter of our food become disposed of so as to be prevented reaching the general circulation as sugar. Any explanatory proposition that is offered must necessarily locate the seat of the disposal as standing between the alimentary canal and the point where the portal blood-stream obtains entrance into the general circulation. If it were located beyond this point, unless the capacity existed, which may be confidently said not to be the case, for effecting an instant removal of sugar directly the general circulation is reached, the conditions would be supplied for the urine to be influenced as it is found to be in the diabetic state.

What I have to say with reference to the mode of application of carbohydrate matter within our system fits in with what is observed to occur throughout living nature. The operations of animal and vegetable life are brought into harmony with each other. In one of the simplest of organisms—namely, in the yeast cell—a demonstration is afforded of the occurrence of the operations which I submit lead to the carbohydrate matter of our food being disposed of in our system without the opportunity being given of its reaching the general circulation as sugar and thence escaping as waste material with the urine. It is only gradually and as the result of life-long attention devoted to the subject, in association with unceasing laboratory work, that the knowledge has been acquired upon which the new doctrine is based. Much help has been afforded by the teachings of experience in connexion with diabetes, and whilst these are absolutely irreconcilable with the old doctrine upon which physiologists have been relying, they in the most complete manner fall in with, and give support to, the new one. The subject is fully considered in my work on "The Physiology of the Carbohydrates," published in 1894, and it will only be requisite here to enter into sufficient detail for the comprehension of what is being spoken of. The carbohydrates, as we know, are susceptible of being transmuted from one to the other by increased and decreased hydration. Ferments and chemical agents move them in the former direction, and the operation is one that we have the power of inducing at will. Transformation in the latter takes place to an unbounded extent in the living world, but if we exclude a few special instances of laboratory achievement we have not the power ourselves of bringing it about. The first influence exerted on ingested carbohydrate is by the ferments of the alimentary canal, which hydrolise and carry the insoluble into a soluble form, and thus prepare for absorption. On being absorbed the carbohydrate is brought within the sphere of influence of living matter. In the villi, which constitute the seat of absorption, there are active cells with which the absorbed carbohydrate falls into close relation, and subsequently it permeates the cellular structure of the liver, which thus, as it were, stands in a position to exert a supplementary action, and to complete before the general circulation is reached whatever may have escaped completion in the villi.

Now, by the agency of protoplasmic action or the power possessed by living matter, carbohydrate is (1) transmuted to a lower form of hydration, (2) transformed into fat, and (3) synthesised into proteid. All these operations can be definitely shown to take place in the simple cell organism of yeast as the result of the power with which its protoplasm is endowed, and the power here represented is nothing more than the common property possessed by protoplasm in general of both kingdoms of nature. Whilst ferment action hydrates and breaks down, protoplasmic action dehydrates and builds up, and it is by the influence of this latter power, I contend, that carbohydrate naturally becomes disposed of in the system instead of by ferment action leading to the production of sugar that is fictitiously assumed to undergo oxidation whilst traversing the systemic capillaries.

Between the seat of absorption and a point short of the general circulation being reached by the portal stream of blood, I say, we have to look for the disposal of the carbohydrate derived from our food, and it is by the exercise of protoplasmic power that what occurs is brought about. Ferment action has performed its office within the alimentary canal, in putting the carbohydrate matter, if it should be in a form to require it, into a fit state for absorption. If the disposal is completely accomplished no sugar is left to reach the general circulation, and if none reaches the general circulation there is none to reach the urine. This represents the natural order of things. If, on the other hand, the disposal of carbohydrate by the exercise of protoplasmic power should not be properly effected—if, in other words, the circumstances should be such as to lead to the faulty accomplishment of protoplasmic action, or if, even with a natural state existing as far as the system is concerned, it should happen that the function is unduly taxed by the ingestion of an exceptionally large amount of carbohydrate in a readily absorbable form, especially at a period of fasting, sugar will be permitted to reach the general circulation, and in proportion as this occurs sugar will be found in the urine.

The process of transmutation into the lower state of hydration is exemplified by the production of glycogen in the liver. Carbohydrate which escapes being transformed into fat or synthesised into proteid passes on to the liver and here, according to the evidence presented, it may be looked upon as undergoing, in the first instance, the change of state referred to. It is well known to physiologists that the liver becomes charged with glycogen in proportion to the largeness of supply of carbohydrate with the food. Possessing the colloidal property that belongs to it, it forms a serviceable storage material, which, placed in the position it is, is favourably situated for being gradually utilised by transformation into fat and possibly synthesis into proteid. That it should be destined to come back into sugar to be discharged into the general circulation and conveyed as such to the tissues for oxidation is incompatible with the condition in which healthy urine is found.

It was a subject of dispute in former times whether animals possessed the power of forming fat from carbohydrate. The matter is not now open to question. The power, indeed, is largely turned to account by those engaged in husbandry for the fattening of animals for the table. In the practice of our own profession if we want to reduce obesity we advise the restriction of the carbohydrate articles of food, and conversely we recommend that they should be freely taken if we wish to fatten. For many years the state of the lacteals of the rabbit after a meal of oats has been fixed on my mind. Formerly it stood unintelligibly before me, but now I think the meaning is to be read off. It is common knowledge that after fatty food the lacteals of the dog, for instance, are to be found conspicuously injected with milky chyle. In the rabbit, when in a vigorous but not when in a poor or sickly state, fed on oats and taken at the proper time afterwards, I have seen the lacteals about as fully injected with milky chyle as in the dog after fatty food. Oats in their dry state contain about 5 per cent. of fat, which I am convinced upon full consideration of the matter is altogether inadequate to account for what is observed. The extent to which the villi under the circumstances are charged with fat globules I have represented by photo-engravings from micro photographs in my work on "The Physiology of the Carbohydrates." It is admitted that animals are fat producers from carbohydrate, and with its

Digitized by Google

production in the villi it reaches the system and subsequently passes on in precisely the same way as fat derived from without. In the one case we have to deal with fat emanating from a ready formed supply and in the other with fat formed by the protoplasmic agency of the cells of the villi, for it is not for a moment contended that what occurs is of the nature of a mere chemical transformation. As carbohydrate may happen here to be applied to fat production, so have we a provision in the direction wanted for preventing its reaching the general circulation as sugar. There are grounds also for believing that a further formation of fat is effected by the protoplasmic agency of the cells of the liver.

That carbohydrate can be turned to account in contributing to proteid production is demonstrated by the growth of the yeast cell in a medium containing no other source than sugar for the carbon constituent of its protoplasm. Further, carbohydrate is susceptible of being cleaved off from the proteid molecule. The proteids entering into our constitution do not enter the system in a ready formed state. The proteid matter of food is as a first step towards its application to the purposes of life broken up by the ferment agency of digestion. The absorbed products of digestion then fall into relation with the living protoplasm of the cells of the villi. Peptone, which is recognisable previously to the occurrence of absorption, now becomes lost sight of, and in view of all the circumstances existing it may be taken as reasonably permissible to conclude that through the instrumentality of protoplasmic action an extensive building up of proteid goes on in the villi.

By synthesis into proteid carbohydrate matter is placed in a position to be susceptible of transport through the system without running off with the urine. At the same time it is evident that its liberation from the locked-up state into a free form can be most easily effected in the presence of suitable conditions. The lactose of milk cannot reconcilably with our collateral knowledge be conveyed as such to the mammary gland, but must constitute a cleavage product resulting from the effect of—may it not be said?—ferment agency existing within. In the grave form of human diabetes, as well as in the experimentally induced phloridzin and pancreatic diabetes, sugar is drawn from a source other than the food, and the large quantity that can be eliminated testifies to the abundant store of locked-up carbohydrate that must exist ready to be set free when the requisite agent for effecting the purpose is present, just as the sugar in amygdalin is set free in the presence of emulsion.

What has been said of the villi gives them a position of great importance in relation to the assimilation of food, a process that may be naturally looked for to immediately follow absorption. At a period of fasting the amount of sugar in the portal blood practically stands in accord with that in the blood of the general circulation. After the copious ingestion of carbohydrate food the amount of sugar in the portal blood rises, and I have known it reach as high as between 4 and 5 per 1000. The circumstances are such as to lead to sugar being absorbed in too large a quantity to be fully assimilated or disposed of in the villi, and the portion that has failed to be assimilated reaches the portal blood and gives to it a fluctuating condition dependent upon the food. If there were no further provision existing for the purpose of assimilating this sugar and checking its passage into the general circulation we should be thrown into a more or less pronounced glycosuric state after every meal in precisely the same way as, in fact, occurs with the subject of alimentary diabetes. The liver, however, intervenes between the portal vein and the general circulation, and here a supplementary action is performed which, if complete in checking the flow of sugar onwards, protects the contents of the general circulation, and hence the urine, from being influenced in relation to sugar by the food ingested. If the supplementary action is incomplete the blood and urine become influenced, and in proportion to the incompleteness so is the extent of glycosuria. The entry of sugar into the general circulation constitutes the unnatural and not the natural occurrence. In order that we may be kept free from glycosuria sugar must be kept out of and not thrown into the general circulation.

(To be concluded.)

MEASLES AT SWANSEA.—Three of the schools of the Swansea School Board have been temporarily closed owing to an outbreak of measles in several districts of the borough.

ON SOME POINTS IN CONNEXION WITH CARCINOMA UTERI.[1]

BY MAY DICKINSON BERRY, M.D., B.S. LOND.,
LATE PATHOLOGIST TO THE NEW HOSPITAL FOR WOMEN.

THE points I have specially tried to investigate are (1) the conditions under which carcinoma uteri arises; (2) the course and duration of the disease where no radical operation has been performed; and (3) the results of vaginal hysterectomy. I have consulted notes of cases in the Middlesex Hospital cancer wards, the Royal Free Hospital, the Chelsea Hospital for Women, and St. George's Hospital, thanks to the kindness of Dr. Duncan, Dr. Hayes, and Dr. Dakin. Mrs. Scharlieb and Mrs. Boyd have allowed me to make full use of their cases of operation at the New Hospital for Women, for which I tender many thanks. The mass of material is considerable, but when we have to depend largely on notes taken by others, especially by students, it is often difficult to obtain systematic information. I have collected notes of 143 cases of inoperable carcinoma uteri from the cancer wards of the Middlesex Hospital, and 75 cases from other hospitals, and have endeavoured to investigate the subject on somewhat the same lines as Oscar Müller, of Breslau,[2] and Albrecht Tanner, of Berlin,[3] in the papers they published dealing with all the cases of carcinoma uteri, operable and inoperable, seen at their respective clinics during a period of some years.

Influence of age.—First, as regards the age at which the disease is likely to commence. In Table I. are shown the ages at which the symptoms appeared in the cases I have collected and in those of the German writers above mentioned; the latter are given for comparison.

TABLE I.

The figures from the different sources in the foregoing table correspond very fairly with one another. In the first three groups the maximum number of cases occur between the ages of forty and forty-five years, but both the preceding and the following five years show very large numbers also. In Müller's cases the maximum is between the ages of forty-five and fifty years, and the fifteen years between the ages of forty and fifty-five years show slightly more cases than does the period between thirty-five and fifty years—the fifteen years containing the maximum in the first three groups. Before the age of thirty years all agree in showing very few cases; after thirty-five years of age there is a rapid increase. After fifty-five years all show diminution, but the descent is not so rapid as the ascent, the ages from sixty-five to seventy years being equal to those from

[1] A paper read at the Registered Medical Women's Association on July 6th, 1897.

Digitized by Google

twenty-five to thirty years. That this does not represent equal liability to the disease is evident from the fact that there are far fewer people alive at sixty-five than at twenty-five years of age and therefore the diminution in liability to carcinoma as age increases is far less than would appear from the figures in the table. Between the ages of twenty and twenty-five years I found only one case. The patient was a nurse, a single woman aged twenty-two years. There was a history of six weeks' hæmorrhage, but no other symptom. When seen a "warty, tuberous condition of the cervix" was found widely infiltrating the vagina and quite inoperable. She died only two months later, apparently from uræmia. The condition described sounds more like carcinoma than sarcoma, but the case is certainly an unusual one both as regards the age of the patient and its duration.

Duration of the disease.—The next table (Table II.) shows the duration of the disease according to the ages of the patients. The last four columns in the table represent the same cases arranged in two groups—viz., those under and those over forty-five years of age. This table shows that the commonest time for the disease to last is from one to two years, about half as many cases lasting under one year and from two to three years respectively. A considerable number lasted from three to four years; above four years very few. It will be seen that to some extent the younger cases are the more rapid—i.e., there is a larger percentage of short cases among the younger and of long cases among the older patients, but this is not very marked. Two out of the six cases where the disease lasted six years were under thirty-five and forty years respectively. In these tables I have only taken those cases with a definite date for the onset of symptoms. In nearly all the cases this was hæmorrhage. Cases of old uterine disease with history of bleeding for many years have not been included. I have included one case where the symptoms lasted for nine years. Here there was history of bloody leucorrhœa beginning at the age of fifty-five years with apparently no previous uterine trouble, but there was no distinct evidence that the carcinoma existed during all these years. Of course, in most of these cases there is no definite evidence that the onset of the symptoms corresponded with the beginning of the carcinoma; it is quite possible that in many cases the disease may have existed considerably longer. I have attempted to trace the subsequent history of the patients with inoperable carcinoma uteri who had been in the New Hospital for Women—most of them for curetting. Of these I have only been able to obtain tidings of seventeen. Thirteen out of the seventeen are dead—eight died within one year, three between one and two years, and two nearly three years after leaving the hospital. Four are still living at periods of nine months, twenty-one months, two years, and four and a half years since they were discharged. The first of these is fairly comfortable, the next two are in the last stage of the disease and very ill. The remaining case is an interesting one. The patient was thirty-seven years of age when the symptoms began; when admitted she had had bloody leucorrhœa eight months, the uterus was fixed, and there was considerable infiltration of the left parametrium. Carcinoma uteri was diagnosed, but the case was considered too advanced for operation. This was four and a half years ago; since then she has had comparatively little trouble and has been able to do her housework as usual, she has no pain except at her menstrual periods, which she says continue regular, but are profuse. Constipation is her chief trouble. Per vaginam there is a large infiltrating mass quite fixed and apparently filling the whole pelvis. It is surprising that this should have caused so little inconvenience. The duration of the disease in this case is the more remarkable as occurring in a comparatively young woman. Dr. Sinclair records a case the converse of this—i.e., a rapid case in a patient over sixty years of age.[4] When seen by him there was a distinct ulcerating nodule on the cervix; six weeks before this another practitioner had found a doubtful nodule. Vaginal hysterectomy was recommended, but the patient took six weeks to make up her mind. When she returned after this interval the vagina was filled by an ulcerating mass and the case was much too advanced for operation. It is evident from these and other cases that the duration of carcinoma uteri is extremely variable. Unfortunately there are not enough records of the pathology in the notes I have collected to enable us to examine the relationship between this and the duration of the cases.

Influence of previous health.—Another question which suggests itself is, Are there any points worth remarking in the previous history of the patient? As regards the general health there appears to be nothing special. There is history of old uterine disease in twenty-two cases—i.e., 10 per cent. In many of these the history is vague, mostly of leucorrhœa of many years' standing; four were previously treated for endometritis and "erosion"; two had had polypi removed fourteen and sixteen years previously, one, a woman of sixty-three years of age, had worn a pessary for prolapse for eight years. Considering the prevalence of uterine trouble, such as chronic leucorrhœa, especially among the class from which these patients are drawn, this number does not seem large—scarcely enough to suggest any causal relation to the subsequent carcinoma. Association with pregnancy was found in nine cases out of the 143 from the cancer wards of the Middlesex Hospital. In four cases the symptoms appeared during pregnancy in patients of the ages of thirty-five, thirty-seven, thirty-eight, and thirty-nine years. In three of these cases labour was difficult but terminated naturally, in the fourth Cæsarean section was performed, and the patient died after the operation. In the other three

cases the duration of the disease was for periods of eighteen months, two years, and three and a half years respectively. In three cases, one forty and two forty-one years of age, the symptoms came on immediately after confinement. One patient died three years later; the end of the others is not recorded. In two cases the symptoms dated from a miscarriage. One of these, a patient aged twenty-six years, when seen six months later was found to have too advanced disease for operation. The other, aged forty-three years, had had bleeding for two years when first seen. This gives a percentage of rather under seven of cases associated with pregnancy. Müller finds a much larger number among his cases—viz., forty-six, or 14 per cent. Of these nineteen were over thirty-eight years of age, which he mentions as possibly supporting Cohnheim's theory that early carcinoma uteri is favourable to conception. He considers that the disease is likely to make rapid progress during the lying-in period, and instances a striking case as evidence of this. The cases I have cited do not show any marked rapidity of the disease, on the contrary many of them are of more than average duration, and those patients who left the hospital and were lost sight of probably lived a considerable time, as none of them appeared to be in the last stage of the disease.

Influence of fertility.—It is often stated that carcinoma uteri is prone to attack those who have borne a large number of children. Most of the patients who developed carcinoma in connexion with pregnancy had had fairly large families—i.e., from six to twelve children; in one case there had been a previous confinement within ten months. As regards fertility in the cases in general, in 141 instances where particulars on this head are given I find 133 married patients with history of 622 children and 135 abortions, giving an average of 5·7 pregnancies to each. Eight single patients, all nulliparæ, are left out of account. Among these cases are 41 with but one or two pregnancies each; but, on the other hand, there are several with a very large number; 19 patients had had twelve or more, 4 of these from fifteen to nineteen. It is noticeable that some of the largest families were found among the patients who were attacked by cancer when over sixty years of age, the average number of pregnancies among those patients being 7·6. Müller obtained an average of 5·37 pregnancies in 528 cases, which is almost the same as that given above. This, he points out, is by no means a very high figure. In Prussia the general average is said to be 4·6 children; what the average is in England I do not know. Sinclair in 100 cases of carcinoma uteri examined in Manchester found a somewhat higher average—viz., 5·8 children per head. Among these cases there were no barren women. In the 141 cases I have referred to there were 17 nulliparæ—i.e., 13 per cent. Eight of these were single and nine married. The percentage of single women is just under 6, which is low, as, according to the Registrar-General's return, about 16 per cent. of women over thirty-five years of age are single. Müller found only 28 nulliparæ, or only 5·3 per cent.; he does not say how many of these were single. Compared with the statistics of carcinoma of the breast these numbers are very low. Bryant found in 600 cases 20 per cent. single women, and 28 per cent. of the married women were nulliparæ.[5] The ages at which the nulliparæ were attacked show no marked deviation from the general tables; the maximum was between forty and fifty years; two of the single women were over sixty years; and one, the case already referred to, was under twenty-five years. These statistics do not show any special preponderance of nulliparæ in the post-climacteric cases, but of course the number is too small to be of much value. Unfortunately, evidence as to how many, if any, cases of carcinoma corporis there were among them is wanting.

Influence of the menopause.—Müller divides his cases into three classes—those attacked before, those attacked during, and those attacked after the menopause. He draws attention to the fact that his tables show a decidedly late average for the occurrence of the menopause, especially when taking into account the class from which the patients were drawn, for he considers that the menopause occurs earlier in the poor than in the more prosperous classes. In 60 per cent. of Müller's cases the menopause did not take place till after forty-eight, and in 35 per cent. not till after fifty. I find a note of the occurrence of the menopause in 54 cases, as in Table IV.:—

[5] Erichsen's Science and Art of Surgery, vol. ii., p. 800.

45 - 50 ,,	24	45 - 50 ,,	81
50 years and over	19	50 years and over	70
Average a little under 48.		Average a little over 48.	

The average age at which the menopause occurs is given variously by different writers, some putting it at forty-five years, others a few years later. By way of investigating this point I noted the date of the menopause in 200 out-patients taken at random, excluding those with uterine diseases as much as possible. The result of this is shown in the second part of Table IV. The two parts of the table correspond almost exactly. In both the average age is forty-eight years; in the first there were 35 per cent. and in the second 34 per cent. of cases of menopause at the age of fifty years and over. In these cases therefore there is no evidence that the menopause tended to occur later than usual. Müller notes among his cases two of exceptionally late menopause—viz., over sixty years, one case certain and the other rather doubtful. In the cancer wards of the Middlesex Hospital there was one case of menopause at fifty-eight years apparently, and another where the patient was positive that the catamenia did not cease till the age of seventy years, the symptoms of carcinoma appearing four years later. There are several questions which arise in connexion with the menopause. First, what length of time elapsed between this and the onset of the cancer, and is there evidence of anything approaching a constant relation between the two? In the fifty-four cases under discussion the interval was as follows: under one year, 3 cases; from one to two years, 6; from two to five years, 14; from five to ten years, 12; from ten to twenty years, 14; and over twenty years, 5 cases. It may be asked further, Are the cases of late carcinoma also cases of late menopause? Taking the thirteen cases of cancer arising in patients over sixty years of age there were six cases of menopause before and seven after the age of forty-eight years, which corresponds with the proportion in the general tables. Conversely, taking the cases of menopause after fifty years of age, the interval nearly corresponds to the general average, but in no case is it under one year and in only two under five years. In the cases of early menopause—i.e., before the age of forty-one years—the interval was as follows. In two cases of the menopause occurring at thirty-one years of age the intervals were one year and thirteen years; in one at thirty-two years of age the interval was eleven years; at thirty-nine years of age it was a few months; in two cases at forty years it was twenty-four and twenty-six years respectively. In so far as any conclusions may be drawn from such a small number of cases it would appear that both in cases of early and late menopause there is a considerable and very variable interval; this is greater on the average in the early cases, implying that the age has more to do with the etiology of the disease than the menopause, and pointing to the conclusion that when once the menopause is established it ceases to be a predisposing cause—if, indeed, it ever is one. As regards the cases where carcinoma arises during the menopause it seems to me very difficult to decide which they are unless the patient has been examined before the disease appeared as the irregular hæmorrhage may be due to either cause.

Influence of heredity.—The question of the influence of heredity upon the occurrence of carcinoma is one that deserves brief mention and is a point which appears to have been carefully investigated in the cases in the Middlesex Hospital. Among 150 cases there are 28 with some family history of cancer. In 2 cases three members of the family had been affected, in 6 two members, and in the remainder only one member. There were 16 cases of carcinoma uteri in the family history of 13 patients. In 5 of these the mother was affected, in 6 sisters, in 2 a grandmother, in 3 aunts. The double histories were mother and sister, two sisters, and two aunts. There were 12 cases with a family history of

Digitized by Google

carcinoma in other parts of the body; breast: 6 cases, two sisters, one grandmother, and three aunts; liver: 2 cases, father and sister; tongue: 1 case, an uncle; throat: 1 case, a father; nose: 1 case, a grandfather; and stomach: 1 case, relationship unknown. In 10 cases the locality of the disease is not given—it occurred in 2 mothers, a grandmother, a brother, a sister, an uncle, and 4 aunts. The preponderance of females to males in this series is very large, being as 31 to 7. The number of cases of carcinoma uteri is also remarkable and suggests more than accidental coincidence, but the total number of cases with family history of cancer is not large, being under 19 per cent. It is worth noting that in all these patients the existence of a family history of phthisis has also been inquired into and has been found in 27 per cent.

The value of hysterectomy.—With regard to this point it is still necessary to go to the Continent for statistics of any magnitude. The number of cases in many London hospitals where the operation has been performed sufficiently long ago to be of value as regards ultimate result is comparatively small, and many patients seem to have been lost sight of. In published records I have found no larger series than twenty cases, and in many of them several were only recent operations when recorded. On the other hand, as is well known, many French and German surgeons have published series of cases extending over many years where nearly all the patients have been kept in view after their operation. Krukenberg[6] has published 235 cases, Münchmeyer 80,[7] Richelot 68,[8] and many others equally large numbers. At the New Hospital for Women there have been 18 cases of vaginal hysterectomy for malignant disease of the uterus up to March, 1896; these were mostly cases under the care of Mrs. Scharlieb. In 1893 there were 5 cases; 2 died after the operation, 2 remain cured (a case of carcinoma cervicis involving both lips and a case of carcinoma corporis), and 1 recurred (a case of carcinoma cervicis with slight infiltration of the vaginal wall). In 1894 there were 5 cases; of these 2 were for sarcoma, 1 died (an advanced case with considerable infiltration), 2 remain cured (a case of spindle-celled sarcoma and a case of early epithelioma cervicis), and 2 recurred (a case of sarcoma and one of epithelioma with slight infiltration of the vaginal wall). In 1895 and 1896 there were 8 cases; one was sarcoma, 5 remained cured (carcinoma corporis; nodular growth on the cervix with another nodule at the internal os; squamous epithelioma with moderately deep ulceration; carcinoma of the cervical canal; and early carcinoma of the cervix); and 2 recurred (a case of sarcoma and one of advanced squamous epithelioma). In this series, therefore, there are three deaths, five recurrences, and ten cures up to the present date. In the cases of recurrence the disease reappeared in all the cases within a year, and in all but one within seven months. Both the patients in the cases of sarcoma were dead within a year; the three patients suffering from carcinoma lived one and a half, two, and three years respectively. In 1894 Dr. Gow[9] published a series of 8 cases of vaginal hysterectomy with no death, and he has kindly inquired into their subsequent history at my request. Of these 8 two have been lost sight of; they were probably cases of recurrence. Three cases recurred (the first immediately—a case of lympho-sarcoma who died in five months; the other two were cases of advanced carcinoma cervicis recurring at a few weeks and eighteen months respectively; one is a case of probable recurrence (this was a case of carcinoma affecting the whole canal; the patient remained quite well for three and a half years; then a suspicious nodule was found over the sacrum, which showed a tendency to grow). Two remain cured (one certainly a case of carcinoma of the whole canal; the other a case of carcinoma corporis, was well when last heard of. Both were operated on four years ago). In this series nearly all the cases are of columnar celled carcinoma; in the former there were a considerable number of squamous-celled epithelioma—viz., two among the cures and two among the recurrences. The case of sarcoma showed the same rapid course as in two of Mrs. Scharlieb's patients.

[9] The Practitioner, 1894, p. 161.

With regard to the degree of malignancy of the different varieties of carcinoma of the cervix Krukenberg gives the following returns. Of cases of early carcinoma of the cervical canal, 66 per cent. cures; superficial squamous epithelioma of the portio vaginalis, 63 per cent. cures; small cauliflower growth from portio vaginalis, 57 per cent. cures; advanced carcinoma of the cervical mucous membrane, 41 per cent. cures; carcinoma of the cervical wall (? glandular), 40 per cent. cures; large cauliflower growth from portio vaginalis, 37 per cent. cures; and deeply ulcerating squamous epithelioma, 20 per cent. cures. This is certainly a high percentage of cures. The proportion of cures to recurrences recorded by various surgeons is as follows: Fritsch, 60 cases, 47 per cent. cures; Leopold, 80 cases, 56 per cent.; Mangiagalli, 83 cases—advanced carcinoma 20 per cent., and early carcinoma 50 per cent.; Krukenberg, 197 cases, 41 per cent.; Hofmeier, 60 per cent.; Schauta, 47 per cent.; Schroeder, 20 per cent.; Olshausen, 41 per cent.; and Richelot, 40 per cent. The number of cases from which these latter percentages are drawn is not given.

In these statistics only cases operated on over a year previously are included; cases of death from operation are left out of account. The general average amounts to 41 per cent. cures. The percentage of cures must vary considerably, as is shown in these figures, according to what different operators consider the limits of operation. Some of the surgeons mentioned above regard fixation of the uterus as a contra-indication in all cases; a good many operate in spite of some degree of fixation, and this on two grounds: some because they maintain that the fixation may be due to inflammatory thickening, and that it is impossible to diagnose this with certainty before operation, and others because even if the disease has spread beyond the uterus they still aim at removing it entirely. But there are few among the names cited who operate under the latter condition, at least if it is known beforehand, and none, I believe, who favour the wider operations of Kraske, Mackenrodt, and Zuckerkandl.

Table V. shows the date at which recurrence occurred in 189 cases gathered from different sources. It will be seen that 140 cases recurred during the first year—that is, 74 per cent. nearly; during the second year 25 cases, or 13 per cent.; during the next three years the number is small, but remains nearly equal, and even between five and six years after operation there are three cases of recurrence. It is evident, therefore, that when the first year has passed the chance of recurrence very much diminishes, but it is impossible to say when it disappears, if, indeed, it ever does so. These tables include many cases which had only been operated on one or two years before publication, so it is evident that the true percentage of late recurrences is not given. The cases of late recurrence are certainly very curious and are not a pleasant fact as regards the prognosis after vaginal hysterectomy. Among Dr. Gow's cases there

is probably one—the patient who remained well for nearly four years and then developed a nodule in the hollow of the sacrum. Among a series of four cases which Dr. Cullingworth published in 1890, and in all of which the subsequent history has been followed,[10] there is one that is interesting from this point of view. The patient was forty-seven years of age; vaginal hysterectomy was performed for columnar-celled carcinoma of the cervix. She had perfect health for nearly two years and then developed symptoms of intestinal obstruction. Colotomy was performed, but the patient died two weeks later. Post mortem two inches of small intestine were found embedded in the scar, and one gland was found to be infiltrated with carcinoma. This case is interesting for two reasons: first, as showing a condition which would have doubtless made it ultimately one of recurrence; and, secondly, as illustrating a possible danger as an after result of vaginal hysterectomy, which is sometimes overlooked.

It will be seen that in the preceding paper an attempt has been made to bring forward certain facts concerning carcinoma uteri. Some of the points investigated have given negative results, in others the data are scarcely large enough to justify any definite conclusion, but each year will produce better material and more evidence as to the value of hysterectomy in malignant disease, and I hope to continue the study of this interesting subject.

Welbeck-street, W.

REMARKS AND SUGGESTIONS WITH REGARD TO DISINFECTION OF CLOTHES BY HEAT.

BY A. F. MESSITER, M.R.C.S. ENG., L.R.C.P. LOND.,
MEDICAL OFFICER OF HEALTH TO THE ISLE OF AXHOLME DISTRICT COUNCIL.

PROBABLY anyone connected with public health work will readily admit that the sanitary control over an infectious disease such as scarlet fever in rural and the smaller urban districts is in the highest degree unsatisfactory. There are obvious difficulties in the way of compulsory removal under a magistrate's order to the cottage isolation hospital probably several miles distant, and in a labourer's cottage or small farmhouse isolation during desquamation is never carried out. When desquamation has ceased the most obvious factors in the dissemination of the disease are (1) the house; (2) the person; and (3) the patient's clothes.

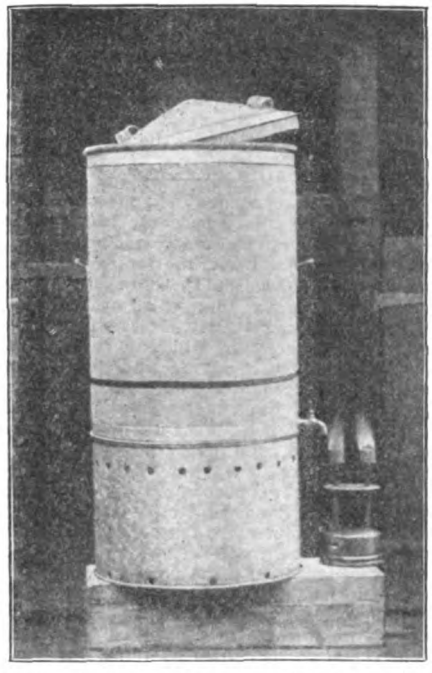
To artificially disinfect a house may be theoretically possible, but from a working point of view the thing is an impossibility. Complete personal disinfection is probably quite attainable, but seldom or never attempted, outside the walls of a well-organised fever hospital, and it is a matter worthy of consideration whether a sanitary authority ought to allow a child to resume school attendance unless the naso-pharynx and auditory meatus have been sprayed or irrigated with some antiseptic solution. Complete sterilisation of clothes can be made an absolute certainty, but we are usually content to advise people to boil and wash infected clothes and our advice is hardly ever honestly carried out. If the disease spreads we tell our district councils that they must expect dissemination in the absence of a portable steam disinfector, the price of which is generally quite sufficient to check any budding enthusiasm on their part. We attempt to eliminate factor No. 1 for the sake of appearances, I suppose, but Nos. 2 and 3 we leave entirely to chance.

My object in this paper is to point out a cheap and easily attainable method of disinfecting clothes by steam, and before doing so I venture to think that a few observations on dry and moist heat will not be out of place. The following facts are probably already well known to the majority of the profession, but have not, I believe, been digested to the extent of their general application to every-day efficient use.

Dry heat.—"For the complete destruction of organisms in the absence of spores exposure to dry heat at a temperature of 120° C. for at least an hour and a half is necessary. Koch found that spores of anthrax required for their destruction dry heat at 140° C. maintained for three hours" (Pearmain and Moor). Ransom's dry heat apparatus is usually worked at 124° C. for two, four, or eight hours; any higher temperature than this gives rise to the danger of scorching cotton and woollen goods. Dr. Whitelegge experimenting with this temperature found that a thermometer placed beneath only two layers of blankets after eight hours registered 110° C., which is 10° C. below what is necessary to destroy organisms without spores and 30° C. below what Koch found necessary to destroy spores of anthrax. Dry heat acts by conduction and therefore makes its way through an object very slowly; consequently, the temperature of the inner portions of a woollen fabric may be comparatively low, while the outer portions are scorching, Stoves and hot ovens are therefore not only injurious but useless for the purpose of disinfecting clothes.

Moist heat.—"All pathogenic organisms as yet isolated are killed, when free from spores, by moist heat at 60° C." "Spores of most of the pathogenic bacteria are quickly killed by a very short exposure to moist heat at 100° C." (Pearmain and Moor). Under the ordinary pressure of the atmosphere water boils at 100° C., and the steam given off is at the same temperature. On meeting with an object a fraction of a degree cooler than itself this saturated steam is condensed, and the water which is formed remains at 100° C. so long as there is any uncondensed steam present. If water is boiled under pressure—e.g., of 10 lb.—boiling does not take place until the temperature has reached 115° C. The steam given off is then at 115° C. and is saturated at that temperature, and condenses when it comes into contact with an object a fraction of a degree cooler than itself, the water of condensation remaining at 115° C. "Saturated steam, when it penetrates into the interstices of a body at a lower temperature than itself, such as a blanket or coat, undergoes condensation into water, then occupying only a very small fraction of its former volume. To fill the vacuum thus formed more steam presses forward in its turn, yielding up its latent heat, and becomes condensed, and so on until the whole mass is penetrated" (Parsons). Condensation, therefore, of steam at 100° C. is the essential point in the disinfection of clothes by this method. If, on the other hand, saturated steam—e.g., at 100° C.—is conducted into a chamber heated up to a higher temperature—e.g., 115° C.—it rapidly runs up to that temperature, that is to say, it becomes superheated, and before condensation can occur it must meet with an object a fraction of a degree below the temperature of the boiling water from which it originated, in this case 100° C. Superheated steam is therefore practically the same as dry hot air at the same temperature; and dry heat, we have already seen, is not only useless but injurious.

The inefficiency of superheated steam depends upon the following fact. If ordinary steam at 100° C. is admitted into a chamber (containing clothes) heated up to 115° C. no condensation occurs on the outer layers of these clothes, for the simple reason that the outer layers have become heated above 100° C. Therefore, no germicidal action takes place. When, however, the steam penetrates further into the fabric it meets with a temperature below 100° C., and then condenses. Consequently the inside is sterilised while the outside is not. Esmarch was the first to clearly demonstrate this. In his experiments with superheated steam he found that anthrax spores were destroyed in one minute and a half inside the folds of a blanket where the temperature was 100° C., while those on the outside of the same blanket were not destroyed in twenty-two minutes, although the temperature had reached 140° C. Dr. Parsons found that anthrax spores were destroyed by exposure to steam at 100° C. We may therefore conclude that the greater uniformity of temperature of steam under pressure in all parts of the disinfecting chamber causing increased rapidity of penetration, and not the fact of the temperature being over 100° C., must be the reason for the greater efficiency of the expensive high pressure apparatus for purely disinfecting purposes; at the same time the higher temperature in the fabric operated on would cause more rapid re-evaporation of the condensed steam on the removal of the material from the chamber, and hence greater rapidity in drying.



Koch concluded from the result of his experiments that exposure to a current of steam at 100° C. was the most satisfactory method of disinfection, and Dr. Parsons, in his report to the Local Government Board on "Disinfection by Heat," after giving in detail the results of his experiments on sterilisation of anthrax spores and tuberculous pus by steam at 100° C. states that it may be considered to be established that

Digitized by Google

the complete penetration of an object by steam heat for more than five minutes is sufficient for its thorough disinfection.

The apparatus which I have designed and which has been admirably constructed by Messrs. Bailey Brothers, of Epworth and Bawtry, will be easily understood by a glance at the accompanying illustration. Circular in shape and

made of galvanised iron it measures 4 ft. in height, with a diameter of 21 in. A portion of the height (2 ft. 10 in.) is taken up by the chamber and the lid, which are separated from the pedestal immediately below the level of the tap. Six inches above the tap will be seen a black line which corresponds with a removeable perforated false bottom in the interior. Above the false bottom is the disinfecting chamber; the space below is the boiler. The pedestal is 14 in. high. The chamber and the lid are covered with felt, and the lid is perforated at the top to allow of the slinging of a thermometer and the escape of steam, and by means of a simple contrivance the junction of the lid and chamber is made almost completely steam-tight. The heating power within the circle of the pedestal is derived from an "intensive oil furnace," which throws out an immense heat by means of volatilised petroleum. This heating arrangement (for the suggestion of which I have to thank Mr. Alfred Bailey) does away with all difficulty connected with the construction of a light, portable disinfecting apparatus. The whole thing, lamp and all, weighs only 54 lb. and costs less than a penny to work for one hour; and even when it is full of blankets and clothes the temperature in the middle of them reaches 100° C. in half an hour from the time of the water in the boiler being cold. I find that an inch and a half of water in the boiler is more than enough for one disinfection.

When the clothes are removed they ought to be immediately shaken in the open air and then freely exposed on a clothes line for half an hour, at the end of which time they will be found to be practically dry. This apparatus, which has been adopted by my sanitary authority, can be carried about in a trap with perfect ease, and can of course be enlarged to any extent on the same model with a corresponding increase of heating power.

Epworth, Doncaster.

BUILTH COTTAGE HOSPITAL.—The new cottage hospital for Builth was opened on Nov. 3rd. The chairman of the building committee stated that the late Mr. John Davies, of Wyeside, had bequeathed £6000 to build and endow the institution, and added that the committee had expended £2600 upon the hospital, leaving an endowment of over £3000, but as this was insufficient they appealed for further funds from the inhabitants.

ON POOR-LAW MEDICAL ECONOMICS.[1]

BY THOMAS M. DOLAN, M.D., F.R.C.S. EDIN., J.P.,
MEDICAL OFFICER, ST. LUKE'S HOSPITAL, HALIFAX.

THE title of my paper will, I hope, be justified when I have read the paper. It was suggested that I should write on Poor-law Medical Adminisratiton; but the medical officer is only an adviser, and I have always steered clear of attempting to usurp the position which belongs to you. You will therefore understand that I confine myself still to the same *rôle*, that I simply throw out suggestions or ideas (or shall I say ideals?) on Poor-law medical requirements, while dwelling strongly on general principles which strike me, as a medical man, as applicable to the great problems you have to deal with. I draw, too, on my experience—a ripe one, extending to nearly thirty years in the service.

You all recognise the grave responsibilities and serious duties which fall upon you as guardians in the matter of medical relief—duties and responsibilities which are increasing rather than diminishing. You are discharging in this country duties which in my travels in Germany, France, Austria, and Russia I find are undertaken by the municipalities or corporations. You have medical charge of infants and children, you have hospitals for the sick poor suffering from acute diseases, whilst you also make provision for the incurable, the infirm, the dying, and the aged. And you have also lying-in wards, so that your medical field is all-embracing. You have a large staff of medical officers, nurses, as well as other necessary officials, and your expenses are great, so that economics are worth consideration. It is an old electioneering cry, "Economy with efficiency." Nothing can be truer when applied even to medical relief. For the effective relief of sickness it appears to me that the only true economy is to provide adequate medical aid. If you accept this principle, as it has been accepted by the Bradford guardians, by the Leeds guardians, by the Halifax guardians, my task will be simpler. It is because you believe that the sick poor for whom you are responsible are entitled to fresh air, good baths, skilled nursing, sufficient and unfettered medical attendance—just as the sick poor have in your noble charities depending on voluntary aid—that you have erected hospitals, built nursing homes, increased your hospital medical staff, and generally increased your first expenditure. Effectual medical aid for grave diseases can only be given under suitable conditions.

How does my paper apply? I will come to the heart of the question. Is it economical to supply trained nurses, give good food, increase the staff of medical men, and generally carry on your hospitals on the most improved principles? I will try to answer this, briefly dwelling on a few principles of economy in relation to labour and the working classes.

We have in England, as they have in other countries, a large number called the proletariat—viz., those who give to the State only children and their work. Their economic conditions are such that, provided work be found for them, they are able to live, saving something; but if sickness comes on, bringing with it loss of work and the expenses which sickness entails, this class is at once plunged into poverty. Disease does come, owing to the environment and nature of the work. The unskilled labourer who works in the open air is liable to pleurisy, pneumonia, bronchitis, rheumatism, heart-strain, and many other diseases, whilst he is also liable to injury and to ulcers of the legs from collision with fragments of stone, wood, &c. Now, neglect in many cases of sickness will convert a simple injury into a serious one, and acute disease into a chronic one, with a corresponding drain upon any revenues supplied by private beneficence or public charity.

Early help in sickness is invaluable. This does not merely consist in sending a medical man who gives a bottle of medicine; we now understand that medical relief comprises more than this. I do not undervalue medicine, but other things than medicine are wanted in every case of sickness. What are the requirements? Pure air, pure surroundings, food to build up tissue, and, above all, intelligent application of medical principles which the nurse gives. The consequence is that

[1] A paper read at a Conference of Yorkshire Guardians at Leeds on Nov. 12th, 1897.

Digitized by Google

under such conditions disease is cut short, the period of absence from work is lessened, and the expense of maintenance is diminished. I know this from experience. I have had this economic subject under my eye for the last five years, and I have no hesitation in saying that, at the Halifax Union Hospital, the period of sickness or detention in hospital has been materially cut short in all those diseases which are curable, and in that special class of diseases from which the outdoor worker suffers. Time will not allow me to dwell too long on this point, but I give you three classes of cases:—1. *Ulcers of the legs:* You will find in all your union hospitals numbers of cases of ulcers of the legs which incapitate men from working. These men may remain in hospital for years, but under efficient nursing they are quickly cured. 2. *Pulmonary affections:* This class also gives us patients at all times of the year who are improved by treatment and discharged to work again. 3. *Cardiopaths:* A large number come annually under treatment who are much benefited.

The duration of stay in hospital will afford a valuable index as to the efficiency of your hospitals, and especially cases by our nurses. They are disappointed if the patient remains in a long time—it is a kind of personal reflection; and this is the spirit we desire to encourage in the interest of the patient and of the ratepayer.

Now another economical question comes in here. If you want your nurse to do her work efficiently it is necessary to provide for her suitable accommodation, good food, regular work but relieved from monotomy, and an annual holiday, for nursing work is exhausting. The food of the nurses may be economically managed, even though you do not adhere to a rigid dietary of "beef and mutton" varied by "mutton and beef."

I pass on to the question of hospital dieting. Your medical officer may very materially increase your annual expenditure, and hospital economics are well worth his consideration. Hospital dietaries vary; there is no uniformity; it may not be desirable. I think we do owe to the ratepayers and to our boards some regard to the expense. I believe we do recognise it. I submit to you two sets of diet tables—one from Halifax, the other from Cardiff:—

I.—DIET TABLE, ST. LUKE'S HOSPITAL, HALIFAX.

THOMAS M. DOLAN, M.D., *Medical Officer.*

Cost per week.	No. 1. 2s. 3d.	No. 2. 3s. 5¾d.	No. 3. 1s. 11½d.	No. 4. 2s 5d.	No. 5. 2s. 5½d. 2s. 3½d. 2s. 2½d.	No. 6. 3s. 9½d.	Remarks.
Breakfast ...	6 oz. bread ½ oz. butter 1 pint coffee	6 oz. bread ½ oz. butter 1 pint milk	6 oz. bread ½ oz. butter 1 pint coffee	6 oz. bread ½ oz. butter 1 pint tea	6 oz. bread ½ oz. butter ½ pint cocoa	6 oz. bread 1 pint milk	—
Dinner	3 oz. meat 4 oz. rice 2 oz. bread 4 oz. potatoes	4 oz. cooked meat 8 oz. potatoes	8 oz. pudding ½ pint beef-tea 2 oz. bread	4 oz. cooked meat 8 oz. potatoes	8 oz. fish 4 oz. bread or 8 oz. potatoes 4 oz. chop or 2 eggs 8 oz. rice pudding	4 oz. bread 1 pint beef-tea	Green vegetables occasionally when in season.
Tea	6 oz. bread ½ oz. butter 1 pint coffee	6 oz. bread ½ oz. butter 1 pint milk	4 oz. bread ½ oz. butter 1 pint tea	6 oz. bread ½ oz. butter 1 pint tea	6 oz. bread ½ oz. butter ½ pint tea	6 oz. bread 1 pint milk	—

II.—DIET TABLE, CARDIFF UNION HOSPITAL.

ALFRED SHEEN, M.D., *Medical Officer.*

Cost per week.	No. 2. 2s. 9d.	No. 3. 2s. 7½d.	No. 4. 2s. 2d.	No. 5. 2s. 5d.	No. 6. *	No. 7. 2s.	Remarks.
Breakfast, 8 A.M.	6 oz. bread ½ oz. butter 1 pint tea	8 oz. bread ½ pint milk	—	4 oz. bread ½ oz. butter ½ pint cocoa	6 oz. bread ½ oz. butter 1 pint tea	6 oz bread 1 pint gruel ½ pint milk	—
Dinner, 12.30 P.M.	6 days. 4 oz. cooked meat 12 oz. potatoes Tuesday. ½ pint pea soup 4 oz. bread	2 oz. bread 1 pint beef-tea	Daily. 8 oz. bread 2½ pints milk	3 oz. cooked meat 8 oz. potatoes	8 oz. potatoes 6 oz. fish or 8 oz. potatoes 4 oz. chop 4 oz. bread or 2 eggs rice pudding	Same as house diet	—
Supper, 6 P.M.	6 oz. bread ½ oz. butter 1 pint tea	3 oz. bread 1 pint milk porridge	—	1 pint milk porridge 4 oz. bread	6 oz. bread ½ oz. butter 1 pint tea	—	—

* Cost with beef-tea, 3s. 9d.; with chop, 2s. 10d.; fish, 3s.; eggs, 2s. 8d.

if you confine your observations to acute diseases. The chronic cases are also much ameliorated by efficient nursing and liberal dietary, and a large number are sent out recruited for summer, spring, autumn; probably some come in again during the winter months. The trained nurse will not allow "loafers," of whom there are so many to be found in union hospitals. She is anxious to get her patients well, and nothing can equal the painstaking work done at St. Luke's Hospital, Halifax, in regard to acute disease and surgical

I have estimated, as you see, the cost of these dietaries per week, and one cannot go very far wrong with those dietaries which are made by me the basis of food-treatment.

The sick are placed on one of these scales, but this has to be supplemented and varied, and does not adequately represent all the cost per week. Herein comes waste. The patient is by right entitled to some form of diet, representing so much bread, so much meat, so many potatoes, so much milk, which is drawn each day whether the patient can eat

Digitized by Google

it or not. Here there is room for reform, but I am not prepared with a definite scheme. We have recognised it, and our superintendent has tried to grapple with it in one or two ways. Extra bread is given to those who can eat it between meals from what is left, but it is made more appetising by a little jam or marmalade. Meat left over is made into little hashes, whilst spare potatoes are always used in some little dish. You know from your experience of your union hospitals that the sick cannot eat each day the diet on their bed-cards, but you must have a diet scale, and this must be drawn daily, otherwise the patient will complain. This is one part of Poor-law economics upon which collective wisdom may throw a light.

The dietetic question presents another aspect in reference to the use of stimulants. My rule is the same that I employ with my private patients. I order stimulants, but not in a routine way. Beer is rarely given, never *pro formâ*. Other stimulants are given in medicinal doses, in *ounces*—so many tablespoonfuls so many times a day. I have fully considered this question in all its bearings. I admit that there are many who are brought to the union hospital through drink and improvidence therefrom, but they do not amount to 18 per cent. My statistics on this point agree with those of one of the greatest observers of the habits of the very poor—viz, Mr. Charles Booth—who, inquiring into the condition of 4000 of the submerged, found that of those reduced to poverty 4 per cent. were loafers, 14 per cent. were addicted to drink, 27 per cent. were poor through illness or had been the victims of misfortune, and 55 per cent. were thrown out of employment. So that this reason cannot be legitimately urged—viz., that for the benefit of the 18 per cent. we should penalise the 82 per cent. whose illness may be due to legitimate causes. I admit that the medical officer should exercise vigilance over the use of stimulants, but his hands should not be absolutely tied.

Before passing from the environment of the hospital, where nowadays the sick poor are humanely treated, where dietaries and nursing are ample and where medical aid is of the most effective kind, I might add one or two words on the humanising influence of the nurses, on the healthy influence they exercise on their patients—influences which have to my knowledge extended in many cases outside the hospital walls, leading to a return to better ways on the part of many men and women. We cannot measure in money weight human sympathy or the kindness or devotion to work on the part of the nurses, but yet I venture to say it has to be reckoned with as a great economic force. I also cannot but think that the personal visits of the guardian who disinterestedly and kindly interests himself in hospital work, visiting the wards, encouraging all by his words, lifting the fallen, reproving maybe, but sympathising with deserving objects of charity, must also have a high economic value.

The sick poor who are admitted to the modern union hospital are more fortunate than those who remain outside in their own homes, and my final words will be briefly devoted to outdoor medical relief. The same principles are applicable. Effectual aid is equally desirable. Is it available? You have a large staff of medical officers who are engaged to attend the outdoor poor at their own homes, to give not only first aid, but to attend in prolonged and serious cases of illness. If we look at the economical conditions of this staff we shall find that the principle of economy is very manifest. Medical officers are appointed who have large, sometimes enormous, districts, who find their own medicines and appliances, and who are paid at such a scale that each visit is remunerated at a very low rate.

The old argument is used. The law of supply and demand comes in. If guardians can obtain medical men at such a price, why should they pay more? The answer is not for me to give; but I am anxious to direct your attention to some aspects of these appointments. Efficient aid is what is wanted. Neglect may convert a common cold into a serious illness. The medical officer who is called in ought, in order to complete his work, to be able to prescribe for his patient and also to order any necessary food. It appears to me that it must hamper the medical officer to find all necessaries out of his salary, and certainly as he deals with disease in the most unfavourable surroundings he requires other help. His medicine alone can do very little good unless supplemented by nursing in the houses of the poor. The outdoor Poor-law nurse seems to me a fitting complement to perfect the system. This nurse should visit all cases attended by the Poor-law medical officer, and give force to all the medical directions. She should supervise all removals to hospital, and she should assist in many other ways. I am not in favour of increasing the work of the outdoor medical officer by this—viz., by keeping cases out of the hospital under his care. No, I think that it is better to send into the hospitals all cases that require prolonged or careful nursing and good food. I very much regret to note that there is such repugnance to the workhouse hospitals, that patients remain out as long as they can, often without medical aid, and sometimes only enter to die, swelling the death-rate in our hospitals. The guardians also know that a number of patients are sent in who are approaching their end. It is difficult to know how to deal with this class of cases. In many instances it would be more economical to increase the outdoor relief for the few days such patients may live, besides being more humane. With outdoor nurses this would be possible. We cannot disguise from ourselves that there is, too, a repugnance to apply to the parochial medical officer. This feeling is laudable, but is a reflection on the system which ought not to exist at the present day when guardians are humanising their work. I do not want you to break down the barriers or to make it any easier to obtain *free* medical advice. No, but I do want to convince you that you ought not to give simply *cheap* medical advice; that as you are entrusted by the State with the relief of suffering amongst the poor, you should give effectual medical aid, and and that you cannot give effective aid without the best machinery.

Gentlemen, in conclusion I can only repeat that I am not a *doctrinaire*. I give you my views and suggestions for what they are worth. It needs great care in administering your Poor-law funds, avoiding parsimony as well as extravagance. There never was a time when the needs of the deserving poor were more carefully considered and relieved, and there is no country like England where the sick poor are so tenderly and devotedly nursed. Medical advice in sickness is the great question of the day agitating the philanthropists from one end of England to the other. All kinds of schemes have been formulated to grapple with sickness amongst the labouring poor; but I hold that with an efficiently organised Poor-law system no poor person should dread the approach of sickness, and that for medical aid in sickness there should be no stigma in accepting such aid from the Poor-law.

Halifax

PUERPERAL SEPTICÆMIA TREATED WITHOUT STREPTOCOCCIC SERUM; RECOVERY.

BY EUSTACE M. SWANWICK, L.R.C.P. LOND., M.R.C.S. ENG.,
PHYSICIAN TO HARTLEPOOLS HOSPITAL.

THE above title is used to compare the case with the very full and interesting account of a case of puerperal septicæmia given by Dr. Rawlings in THE LANCET of Aug. 7th last. As in Dr. Rawlings's case, so in mine, there is no account to offer in the way of bacteriological examination.

A primipara, aged twenty-three years, whom I was engaged to attend at the end of July, sent for me on the morning of July 14th, 1897. The labour began about 1 A.M. The head presenting in the third cranial position made the labour slightly less normal than otherwise it might have been. A small quantity of a mixture of chloroform and rectified spirit relieved the urgency of the pain and the child was born at 5.25 A.M. There was a slight perineal tear, hardly to be dignified by the name of rupture, as it did not seem to involve any muscle. Before each infrequent examination my hands were rinsed in a 1 in 1000 solution of perchloride of mercury and lubricated with carbolised vaseline. On completion of the third stage a soluble pessary containing ten grains of iodoform was passed high up into the vagina, a binder applied, and the patient was left feeling comfortable. About 10 A.M. the temperature was 99° F. and the pulse was 84; there was no pain or malaise. In the evening the urine was drawn off with a catheter, well washed in disinfectant. During the 15th the patient seemed to be going on well. On the 16th, at 12.30 P.M., the temperature was 100 8°; at 2.30 P.M. there were pains all over the head, back, and limbs, and a feeling of cold water down the back, but no full rigor; the

Digitized by Google

pulse was 124 and the temperature was 104·6°. I gave a powder of fourteen grains of phenacetin and ordered seven grains to be given every four hours, a mixture containing acetate of potash and tincture of aconite, and an iodoform pessary to be introduced. There was no marked abdominal tenderness, but some tenderness of the fundus was present. Vaginal examination showed a slightly retroflected uterus with puffy cervix. There was no difficulty in reducing the flexion. No malodour was apparent in the scanty discharge. I called on the district professional nurse and asked her to administer night and morning an injection of *hot* solution of Condy's fluid and an enema of one pint of plain water, also hot. I diagnosed the case as puerperal influenza.[1] The tongue was of the influenza variety, moist and slightly furred. On July 16th, at 12.30 P.M., the temperature was 100·8°, at 2·30 P.M. it was 104·6°, and in the evening it was 103°. Subsequently the temperature was as follows:—

Date.	Morning.	Evening.	Date.	Morning.	Evening.
July 17th	101·0°	98·6°	July 22nd	99·8°	100·2°
,, 18th	100·0°	99·0°	,, 23rd	99·8°	98·8°
,, 19th	101·4°	103·4°	,, 24th	98·4°	99·0°
,, 20th	100·2°	102·2°	,, 25th	98·4°	—
,, 21st	100·2°	101·4°	,, 28th	98·6°*	—

* Became subnormal.

On the 17th and 18th she had nocturnal delirium and I prescribed 30 grains of bromide of potassium and one drachm of ammoniated tincture of valerian in two ounces of water; this was to be repeated night and morning when the restlessness was extreme. On the 19th she had diurnal as well as nocturnal delirium. On the 21st I gave her a sulphate of quinine and hydrobromic acid mixture. From the 16th to the 21st the pulse varied from 110 at first to 140; it was generally about 132. On the 22nd I reduced my visits to one each day and the nurse took the evening temperature. On the night of Aug. 26th–27th the patient had chills and pains all over. The temperature was 100·8°. No puerperal condition could be made out. I ordered the mixture of acetate of potash and aconite together with the phenacetin powders. On the 27th, at 10 A.M., the pulse was 108 and the temperature was 99·6°; at 10 P.M. the temperature was 102°. On the 28th, at 10 A.M., the pulse was 108 and the temperature was 99·4°; at 9 P.M. the temperature was 98·4°. On the 29th, at 11 A.M., the pulse was 72 and the temperature was 98°.

Remarks.—Owing to the preliminary diagnosis of influenza I was led to make inquiries about previous illness. The hypothesis is that if there is no influenza at the time of labour or delivery the puerperal trouble begins at the end of the fifth day; if the patient has influenza at the time of labour there is a respite for two and a half days, and the influenza then reappears, generally in a different form, and frequently in a puerperal form.[2] I found that the patient had had chills and pains all over on July 9th, and she had noticed that her feet were swollen on the 7th. The labour was before the expected time, a common occurrence in influenza, and began about 1 A.M. on the 14th. The temperature chart shows on the 16th the rise beginning about 12.30 noon and a high temperature by 2.30 P.M. Except for absence of streptococcic serum treatment I treated the case on general puerperal fever principles, keeping the parts disinfected by Condy's washes and iodoform, while I treated the fever as an influenzal condition, avoiding stimulants and narcotics at first. When the patient was nearly out of danger, and her sister was congratulating herself and me on her recovery, I told her they must look out for a recurrence of the attack in seventeen, thirty-five, or fifty-one days from the commencement,[3] but that if they let me know at once on its recurrence we should probably be able to cut it short in three days. The tongue at that period was of a distinctly influenzal character. Now seventeen days from the 7th, when she noticed her feet swell, brings us to July 24th, when the patient was weak but convalescent in bed; thirty-five days, to Aug. 11th, on which date no new symptoms occurred; and fifty-one days to Aug. 27th. On the night of the 26th the temperature rose to 100·8° and the case ran as described above. As these cases occur so frequently in a more or less distinct form one is disposed to look upon them as a puerperal catarrh of an influenzal nature. The deaths from them are rare if treated as a catarrh. Out of a very considerable number of such cases I can remember only once losing a patient, and I believe that was a case of true "puerperal" fever engrafted on the influenzal catarrh, due to want of cleanliness on the very unprofessional nurse's part and general inattention to directions, the patient from the beginning having to attend to most of her wants as best she could. I cannot call to mind any similar cases anterior to the influenza of 1889, when they became frequent. The milk-supply also is generally unaffected, and if there is any malodour about the discharge it is of a peculiar mousey nature, which I cannot call to mind as occurring in any other complaint. I saw my patient on Sept. 11th and sent her into the country. She nursed the flourishing infant until the middle of October. At this time the child was taken from the breast owing to the nervous condition of the mother, who is to-day (Nov. 16th, 1897) doing well.

There are so many points in common between Dr. Rawlings's case and the above, and the injections of anti-streptococcic serum were in his case, so ineffectual, that it is suggested that we have a catarrhal germ infection not of a streptococcic nature. If the relation of these cases make us all more careful in future to look for the streptococcus it will be the means of our learning to distinguish between the various forms of puerperal fever.[4]

A CASE OF ABSCESS OF THE LIVER; RUPTURE INTO THE LUNG; RECOVERY.

BY T. GLOVER LYON, M.D. CANTAB., M.R.C.P. LOND.
PHYSICIAN TO THE CITY OF LONDON HOSITAL FOR DISEASES OF THE CHEST.

FOR the notes of the following case I am indebted to Mr. Charles Lamplough, resident medical officer.

A man, aged thirty-five years, costermonger, was admitted to the City of London Hospital for Diseases of the Chest on Aug. 5th, 1897, complaining of diarrhœa and pain in the right side. He had never been out of England. His bowels had acted two or three times daily for two years, but with little or no abdominal pain or tenesmus, nor had he noticed any blood in the evacuations. He had had a slight cough for twelve months, and during the three months prior to admission he suffered from "shooting" pains down the front of the right chest, with shortness of breath on exertion. On examination the patient was found to be a well-developed man, though emaciated and anæmic. No jaundice was noted. He had a slight cough with scanty mucoid expectoration and complained of a sharp pain over the right lower ribs in front. The chest was of good shape and expanded fairly well and equally. Anteriorly there was comparative dulness from the lower border of the fourth right rib in the nipple line to two inches below the costal margin; behind, the percussion note was comparatively dull below the inferior angle of the right scapula. Over the dull area the breath sounds, vocal resonance, and fremitus were much diminished, though not entirely lost, but no moist sounds were audible, nor was the voice of ægophonic quality. The heart's apex beat was in the fourth left interspace half an inch "inside" the nipple line. The sounds were free from murmur, the pulmonic second sound being accentuated. The pulse was 92, regular, and of fair tension and volume. The abdomen was slightly distended and tympanitic, not tender, but very resistant. The lower edge of the liver could be indistinctly felt about two inches below the costal margin. The spleen was not palpable. The bowels acted two or three times daily, the stools being large, fluid, and very pale, containing no blood or mucus. The temperature varied from 99° to 101° F. daily. The diarrhœa, pain over the upper part of the hepatic area, the enlarged liver with great abdominal resistance, the diminution of breath sounds, and the slight elevation of the heart without lateral displacement towards the right, together with the remittent temperature, suggested the diagnosis of abscess of the liver. Three exploratory punctures were made into the lower part of the right chest over the painful area, but nothing excepting a little blood was withdrawn. The patient gradually became worse until Aug. 16th, when suddenly at about 3 A.M. he had a fit of coughing, lasting on and off for about two hours, during which he expectorated about six ounces of dark fluid,

[4] Compare also Dr. Groth's case in THE LANCET, Aug. 14th, 1897.

Digitized by Google

of the typical anchovy-paste appearance; this was carefully examined by Dr. J. J. Perkins with a negative result, except that numerous torulæ were found. For the next ten days the man continued to bring up blood-stained purulent liquid, measuring about fifteen ounces daily and of a faint pinkish colour. During this period the temperature fell to subnormal, varying diurnally from 97° to 98°; the diarrhœa continued in spite of careful dieting and the administration of intestinal astringents and antiseptics. It was noticed also that the muscles of the right loin were much smaller than the corresponding muscles on the left side of the spine, though the former reacted equally with the latter to the faradaic current. This condition of the muscles, strange to say, seemed to give the patient no inconvenience in raising himself in bed.

After this the patient began to recover slowly, the expectoration diminished in amount, the cough became less troublesome, and the appetite began to improve. On examination of the chest the physical signs had also notably altered; the upper limit of dulness extended only to the sixth rib in the nipple line, though it remained high in the mid-axillary line, but again descended as it reached the spine, and the lower edge could now be felt just below the costal margin. On auscultation loud friction sounds with râles and rhonchi were heard over the fourth and fifth right ribs anteriorly. On Sept. 8th the patient had another sudden attack of coughing, and this time he expectorated several ounces of bile-stained fluid; excepting that his cough was rather more troublesome for the following fortnight, with an increase of moist sounds over the right lung, his condition was not materially altered. By Sept. 22nd the patient had ceased to expectorate bile-stained fluid, and from this time until his discharge, a fortnight later, his recovery was rapid and uninterrupted, his temperature again reached the normal level, the diarrhœa entirely ceased, the lumbar muscles recovered their normal size, and the patient gained 9 lb. in weight. The man left the hospital apparently quite well nine weeks after his admission and seven weeks after the date of the rupture of the hepatic abscess into the lung.

Remarks.—This very complete case is a good instance of a hepatic abscess occurring without any assignable cause. It also illustrates the fact that cases of abscess of the liver usually terminate favourably after rupture into the lung.

ON THE CLIMATIC TREATMENT OF PHTHISIS.

BY F. RUFENACHT WALTERS, M.D. LOND., F.R.C.S. ENG.,
PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION.

A MAN who is phthisical, or in danger of becoming so, is sure to be recommended a change of climate; but the diversity of climates reputed to be useful to such a patient is at first sight very puzzling. He may be sent for a sea voyage or to an Alpine health resort, to a high and dry tableland or to a low-lying seaside place; and bracing and relaxing, hot and cold places alike, are said to be useful in this same disease. How, then, are we to account for this diversity? Probably in part by corresponding differences in the form of the disease and the constitution of the sufferers, but mainly by the essential climatic factors being comparatively few in number and climate itself but one out of many matters of importance.

We may disregard for the moment the actively inflammatory stages of the disease, which, being usually treated indoors, will do almost equally well in any climate. We may also disregard the advanced incurable forms, in which the utmost that can be done is to prolong life or to render it more supportable. Confining our attention to the places with an established reputation for the *cure* of phthisis we find that with much diversity of minor details they all agree in the possession of certain common characters which we are justified in regarding as the really essential features. 1. In the first place, all such health resorts have a pure air, unvitiated by decaying organic matter or by the impurities inseparable from a large and crowded population. 2. Their atmosphere is free from dust and smoke. Dusty occupations are a fruitful source of lung disease. The dust and smoke of towns are highly injurious to phthisical patients, both from their mineral and organic particles and from the pyogenic and other bacteria which they contain. Even country dust is hurtful, and the most successful health resorts for phthisical patients have a large proportion of grass land or large sheets of water which help to purify the air. 3. These health resorts have a fresh and bracing as well as a pure atmosphere. In the Alpine and hill sanatoria the air is cool even with a hot sun; in the high tablelands the dryness of the air makes it more bracing, while the mornings and evenings are cool and refreshing; by the seashore or on the ocean there is always a cool breeze to temper the noonday heat; so that they all agree in being more or less bracing. 4. But if these health resorts are breezy they must have abundant shelter, for strong winds are very bad for phthisical subjects, exhausting their strength, interfering with respiration, and increasing the risk of chills. Many of the more favoured places are protected against the colder and more boisterous winds by surrounding hills or mountains; in others the necessary protection is obtained by means of forests. 5. These health resorts are also alike in having sufficient fine weather to make it possible to live almost entirely out-of-doors. "If pure fresh air and plenty of it" be the best prescription for phthisical patients, an indoor life should be absolutely forbidden them. Many people are only out-of-doors for two or three hours out of every twenty-four, and spend the former in the vitiated air of towns and the remainder in close and ill-ventilated rooms. A scarcely perceptible breeze out-of-doors supplies a hundred times as much fresh air as enters an ordinarily well-ventilated room. It can therefore be readily understood what a powerful curative agent we have in an out-of-door life in a favoured country or seaside place, and how much depends on the manner of life. Sunshine is very helpful to the phthisical patient, not only because of its anti-bacillary properties, but also (and mainly) because of its stimulating influence on nutrition generally. On the other hand, if rain does not keep people indoors it is also advantageous, as it cleanses the air and lays the dust. Moderate atmospheric moisture is useful in soothing irritable mucous membranes, but it is apt to render warm places relaxing and cold and windy ones depressing. Some of the health resorts for phthisical patients are extremely dry, but others have a moist, cool, still atmosphere, while some are foggy and damp at certain seasons of the year without any very obvious injury to the patients. We may therefore safely conclude that a moderate proportion of wet weather is no serious disadvantage provided that it does not interfere with an outdoor life. Much may also be done by the provision of shelters in the open air to overcome such drawbacks. 6. Prevailing temperatures of themselves have probably only a secondary importance in the treatment of phthisis, as we find a great diversity in this respect among the different health resorts. Very cold places are depressing unless dry and free from wind. Very hot places are relaxing unless dry and breezy. The more robust patients do best where the air is cool and dry, with a fair range of temperature, while more delicate patients require a warmer air and greater equability, which is intelligible in the light of hydropathic analogies. The temperature to be chosen will depend in part on the original home of the patient. French soldiers from the north have been found to be especially liable to contract rapid forms of phthisis when brought to the warmer regions of the south.[1] According to Meissen, North German patients seldom do well at the Riviera; and English authorities agree that the records for English patients are not so good there as at some colder health resorts. Warm sunny lands are extremely pleasant and are very useful in tempting people out-of-doors; but where there are sufficient powers of reaction a colder climate is more likely to cure. There is a mistaken impression in certain quarters that an equable climate is essential to the cure of phthisis. But some of the most useful climates—such as those of the elevated tablelands of South Africa—are far from equable, owing to the extreme dryness of the air; while phthisis abounds in some which have a very small range of temperature. 7. But if a warm and equable atmosphere is not often advisable it is quite otherwise with warmth of soil. A warm, dry soil is essential to a health resort for phthisical patients. It has been clearly proved that phthisis is more common on damp soils and that efficient drainage has lowered the phthisical death-rate. A

[1] Colin: Phthisie Galopante, Paris, 1874.

Digitized by Google

damp soil renders a place less bracing in warm weather, chills the patient in cold weather, and shortens the hours which he can spend out-of-doors. A dry soil, on the other hand, radiates warmth during the cooler hours of the day and helps to cure catarrh. The best soils for phthisical patients are well-drained rock, sand, or gravel. With rock, as with other impervious soils, it is of great importance to have a rapid slope and an efficient outlet for subsoil water. 6. The question of altitude depends on a somewhat different consideration. That it is not essential to cure is shown by the almost equally good results obtained from sea voyages. But there is no doubt that in a certain class of cases great elevation above the sea-level is invaluable in promoting the expansion of sound parts of the chest. Still, we should remember that altitude is only one of the factors of treatment at high levels, which also benefit by their pure bracing atmosphere, their freedom from dust and wind, their abundance of warm sunshine, and in many cases the numerous advantages arising out of systematic treatment in sanatoria. Where these other factors are present we may reasonably expect a large measure of success, even without the advantage of high altitude.

If these, then, are the essential features of a successful health resort for the cure of phthisis, the question arises whether it is necessary, as a rule, to send patients out of this country, and whether we might not find a number of suitable places within our borders which with proper management would do admirably for such a purpose. We cannot, it is true, find Alps on elevated tablelands within our borders; but all the other essential features are to be found in many parts of England, while there are many important advantages in treating the patient in this country. There are many places in these islands with an admirable soil and climate which if suitably arranged would do extremely well for the fresh-air treatment of phthisis. Nor is this merely my own opinion, for many of our leading specialists adopt the same view. The main drawback to the British climate is its large proportion of cloudy and rainy weather. But this is of comparatively little importance if suitable shelters are erected, as in most of the continental sanatoria. We have, on the other hand, a more equable climate than the continental health resorts, while the somewhat greater atmospheric moisture of our drier neighbourhoods would be an advantage in many cases. Some of the best continental resorts have by no means perfect climates. According to Hermann Weber, "There are no perfect climates for invalids A climate with constant moderate variations in its principal factors is the best for the maintenance of health. ..... Such are the climates of England all the year round, and they belong to the most health-giving in the world. ..... They are, it is true, not the most agreeable or exhilarating, but the brightest and most exhilarating climates—such as those of Egypt, Spain, Italy, Greece, Asia Minor—are not the best for health and longevity; they are in many respects inferior to those of England."[2]

If, then, our climate is not unsuitable, it may be asked why our results in the treatment of phthisis are apparently inferior to those of the foreign health resorts. Partly I believe because up to the present many of the best districts have been neglected, partly because we have not taken the trouble (as they do abroad) to correct the natural disadvantages of each place for this purpose, and mainly because our treatment has been adopted too late, has been too short and too much interrupted, and entirely wanting in that systematic attention to details which is found in continental sanatoria. It is, in fact, not so much our climate that is at fault as the use we have made of it. Our bracing places have been left without sufficient shelter against winds, our sheltered places are during part of the year too relaxing, many of our health resorts are too dusty in dry weather, while others are being spoilt by the growth of population and by unregulated building operations. We have, in fact, made no serious attempt to develop our country's resources in this respect and to treat the disease with the continuity which is essential to success. There is no place within these islands where adequate shelter has been provided in the open air for rest and exercise during rainy weather, so that the open-air treatment degenerates into the indoor treatment of phthisis. Although it is admitted that in no other disease does attention to details answer so well as in phthisis, we exercise no continuous supervision over the patient's food, his clothing, attention to the skin, rest and exercise, the ventilation of his rooms, and other hygienic matters which are at least as important as medicinal measures. And this is largely because of the absence of sanatoria for phthisis in this country, and the prohibitive cost, not to say the impossibility, of thoroughly treating the disease on a small scale. There is no place yet in England where the phthisical patient can live for a year or two, with specially arranged grounds and gardens, specially constructed rooms and shelters, and a dietary specially prepared to suit his needs and fancies, while his symptoms are watched from day to day and promptly treated by experienced specialist physicians. And if he does get these advantages under our continental brethren, what wonder if their results seem better than our own? It has been too long the fashion amongst the laity to regard a climate for phthisical patients as a thing mysterious and altogether unattainable in our own land, while they totally disregard the many incidental matters which contribute so largely to the result. If, then, we wish to make a fair comparison between English and foreign climates let us make the other conditions the same. Until this has been done we have no right to conclude that our climate is not adapted for the cure of phthisis. In some other respects the patient who is treated in England already has important advantages which would be sure to tell if more systematic treatment were adopted. He is saved a long and risky journey, remains within easy reach of friends and relatives, and is spared the home-sickness which so often affects the Englishman in a foreign sanatorium. He has the advantage of English nurses—far superior as a rule to the foreign ones—English sanitation, English feeding, and English medical men who understand English ways. At one far-famed sanatorium on the continent there are just two baths in the basement of an annexe which are considered amply sufficient for the cleansing of over 100 patients and a staff of 60, besides other equally striking examples of unsuitability to English ways. If, then, we were to combine the advantages of treatment in England with the systematic methods of the Germans, and transplant a sort of Brehmer-Dettweiler system with suitable modifications on to our own soil, there is little doubt that the results would be at least as striking as they have been on the continent. Owing to fever and other complications it is often undesirable even in an early stage of phthisis to send the patient far from home; the ordinary middle-class household is by no means an ideal place for such a patient and seaside lodgings are still less satisfactory. Even in the homes of the rich it is unusual to find suitable arrangements for such cases, while ordinary hydropathic establishments, being intended for widely different ailments, are quite unsuitable in many ways. A timely resort to a special establishment without the need for a long and fatiguing journey would very often preserve a threatened life, while it would in no way injure the family adviser. The need for such a sanatorium, especially amongst the middle classes, has been so often brought home to me in my professional work that I have for some time past been making preparations to start such an establishment in one of our southern counties if my professional brethren give me the necessary support; and with this end in view I have recently paid a visit to some of the continental sanatoria of the same kind.[3]

What should be the main features of an English sanatorium for phthisis and the methods of treatment I propose to discuss in a future paper.

Welbeck-street, W.

CHIPPENHAM COTTAGE HOSPITAL.—On Nov. 8th the foundation-stone of the Chippenham Cottage Hospital was laid by Lady Dickson Poynder. The hospital, which will supply a greatly felt want in the district, has been liberally subscribed to by the inhabitants of Chippenham. The gifts include £500 from Sir John Dickson Poynder, and the land for the site from Mr. Carrick Moore.

BRISTOL CONVALESCENT HOME.—At the meeting of the committee of the Jubilee Convalescent Home Fund, held in Bristol on Nov. 11th, it was announced that Mr. E. P. Wills had increased the value of his gift to the proposed institution from £10 000 to £20,000. Sir Greville Smith has also subscribed £2000. This will bring up the fund to nearly £80.000. Mr. Wills believes that in a city like Bristol the collection of £100,000 for such a purpose ought not to be a very difficult task.

THE SEASONS AT THE SWISS ALTITUDES, AND WHEN TO SEND OUT PATIENTS.

BY WM. EWART, M.D. CANTAB. AND DURH., F.R.C.P. LOND.,
PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN.

THE Alpine cure for phthisis, regarded not many years ago with incredulity or distrust by untravelled physicians, and hardly known to the great body of practitioners, is now generally accepted in this country; but a practical knowledge of its details has not yet extended for the majority beyond the initial stage in which it was first introduced to our notice. Meanwhile the subject has moved beyond a mere recognition of the fact that an Alpine winter is good for phthisis, and progress has been made both in the selection and management of cases. All cases are not suitable, and in a given proportion of them the responsibility of giving advice must remain an anxious one. It is probably exceptional in this country for phthisical subjects to take the decision into their own hands, as not infrequently happens abroad, and to proceed to Davos without medical advice or even in spite of it. Most patients sent out from England are fit subjects, but too often they do not avail themselves of their opportunity to the full extent under a mistaken idea that it must be winter before phthisis can gain any good in the Alps. This lessens the chances of recovery of so many that it is perhaps less of a presumption than of a duty to mention the impressions gathered during thirteen yearly visits to the Alps in winter.

If health were always the chief and only consideration a long unbroken residence in the high altitude would be the best form of treatment for nearly all sufferers from phthisis. It is, however, the smaller number only who choose to avoid the risk of losing ground again, which too often attends a return to England for the summer months. Still, the colony of permanent residents is a growing one, and it is among them that the most remarkable results are to be seen. They have experience of all the Alpine seasons, and are naturally, therefore, the persons best qualified to form an opinion as to their relative value.

Unfortunately home-sickness and the monotony of hotel life—from which those who occupy their own private homes in Davos are exempt—are important factors bearing upon the advisability of change; and they cannot be disregarded entirely, though some variety might be found within the Swiss altitudes themselves. The summer visit to England will therefore probably continue to be the rule rather than the exception for those who have wintered in the Alps.

It is for those whose illness comes under observation after the close of the winter season that a question arises which is not always answered in a sense conducive to their best interests. Ought they to be made to wait until the following winter? Such a course would mean for them the loss of a golden opportunity, that of applying the remedy at an early period of the disease. A moment's consideration will show that the influence of pure air and high elevation, which are the principal agents of cure, is not limited to the winter. If a summer spent in the Alps is the best of tonics for the overworked and jaded, could it possibly be detrimental to the phthisical? Experience shows that it is good for them; why, therefore, should they be deprived of this help?

As a fact, a climatic advantage is to be gained *at all seasons*, more marked it is true in winter, chiefly on account of the evils attending a winter residence in England, but not on account of any essential therapeutic inferiority of the Alpine summer. It cannot be too widely known that all seasons in the Alps are good for phthisis, and that as soon as a patient has been found fit to travel he cannot defer his journey without incurring a positive loss. A summer in the Alps is the best of all preparations for an Alpine winter. This is also the season of least risk for the invalid, when the journey can easily be so arranged as to break the suddenness of the change to a high elevation, which is always a source of some anxiety. In the depth of winter, too, the sudden change to an intensely cold atmosphere is not in itself desirable or always favourable. These risks are avoided by patients who take up their winter quarters before the weather hardens.

Cases must of course be dealt with on their individual merits and with due regard to all their circumstances, but it may be stated in general terms that the benefits of a residence in the high altitude are largely independent of the season of the year, and that the best time for each patient to start is the earliest that can be safely managed. The melting of the snow in spring and the uncertain and snowy days in the late autumn are the least desirable periods, but the newly arrived patient who spends them with open windows in his room or even, according to the rest-cure now in vogue, in his bed is better off than he would be in England and is turning time to the best account. I have sent patients to the high altitude at various periods in the year irrespectively of seasons without any cause for regret. As regards the flitting of the winter contingent I am in favour of an early rather than a late start, and of acclimatisation rather than of abrupt change in elevation and in temperature. What may be gained by patients going out early is best described in the words of a recent correspondent of mine, an old Davoser who in describing a patient says: "He like others was sent out late last year (the end of November) and thinks he never gained real good all the winter because he arrived so late. This year he asked no advice as to the date, but came early in September, and rejoices daily that he did so, as he has got on steadily and has come in for all this most perfect weather. We are having a record autumn. Our autumn is always lovely, though rarely so lovely as this. This is the thirty-first day of fine weather—days not to be described, sun ablaze all day, not a particle of moisture, no clouds, no wind, about 8 to 15 degrees of frost at night, making the days deliciously bracing, and yet they are warm, almost like summer at midday. Of these thirty-one fine days only three or four have been cloudy, but none bad. All this time in the lowlands, even up to two stations above Landquart, and almost everywhere in England, a damp raw mist prevails; and yet we hear from people in England that they are coming out here the end of November, but that they are advised not to come till then."

Curzon-street, W.

MEDICAL HÆMORRHAGE.[1]

BY FREDERICK J. SMITH, M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL.

THE term "medical hæmorrhage" is one which does not require much explanation. Bleeding is usually thought of, perhaps, as peculiarly the province of the surgeon but the instances are by no means few in which it forms a very important feature in strictly medical cases; and when it does thus occur it is so terrifying to the patient and causes such anxiety to the attendant medical practitioner that no excuse is needed for bringing the subject forward; it is imperative on us all to be as sure as possible of the ground on which we stand when attempting to control it. To give a clear idea of my meaning of the term I offer the following list of cases to which it is applicable. All intracranial hæmorrhages not due to violence; hæmorrhages appearing from the mouth or nose, as "spitting or bringing up of blood"; epistaxis of youth or old age; bleeding from spongy gums or pharyngeal varicose veins; aneurysm of the aorta; hæmorrhage from the lungs in bronchitis, pneumonia, phthisis, emphysema, malignant disease, &c.; hæmorrhage from the stomach or duodenum; hæmorrhages appearing from the anus either as blood or melæna, or in typhoid fever and other forms of ulceration—e.g., tuberculous or dysenteric; gastric hæmorrhage if not vomited; hæmorrhage from piles internal and external; hæmorrhages appearing from the urethra as blood in the urine; from bladder or kidney, from the vagina in women, metrorrhagia, menorrhagia, or post partum hæmorrhage; and subcutaneously—purpura, idiopathic or rheumatic, &c., and scurvy. A mixed class of cases is due to serious disease—leucocythæmia, acute yellow atrophy of liver, some other forms of blood poisoning, and hæmophilia. This list, probably incomplete, is sufficient to show how important and frequent is that loss of blood which may be termed medical and concerning the treatment of which I wish to mention a few points.

[1] A paper read before the Hunterian Society on Nov. 10th, 1897.

Digitized by Google

The cases divide themselves very naturally into two groups—(1) those with some severe, perhaps even necessarily fatal, constitutional or general dyscrasia or diathesis; and (2) those without such concomitant. The first group, containing purpura, scurvy, hæmophilia, leucocythæmia, blood poisoning, &c., is perhaps the most interesting from the great obscurity of the pathology of any member of it, but to discuss it at all fully would occupy too much space. Suffice it to say briefly that in scurvy good and proper food is all important; in purpura, if of rheumatic origin, Dr. S. Mackenzie swears by turpentine; if due, as so many cases of mild purpura are, to a chronic lack of good nourishment, especially of vegetable origin, the remedy is tolerably obvious — to supply this want — and the cases get well as a rule; in severe purpura (so-called hæmorrhagica) and leucocythæmia treatment is of little avail, though the most hopeful would appear to be large doses of calcium chloride both internally and applied as a styptic; Professor Wright has shown that this, at any rate in hæmophilia, is of considerable service. But in all these diseases and others of the first class we are trying as far as possible to cure a tendency to bleed; it is comparatively seldom (and then the principles laid down below will apply) that the external appearance of blood is of such character or amount that we are called upon to check the bleeding itself, and it is to the immediate treatment of actual hæmorrhage that I wish to direct attention, commencing with the assumption that both the blood and the vessels are healthy in general with merely a local lesion of the latter, and proceeding more especially to the inquiry, what place, if any, have ergot and astringents in the treatment of the condition. My attention has been particularly drawn to the subject in consulting practice—the cases are of such a startling character as to naturally suggest a second opinion—and my almost invariable experience is that ergot has been freely administered directly any severe hæmoptysis or hæmatemesis has appeared. Now underlying this routine practice I am convinced that there is a serious fallacy.

The following is perhaps the most marked example I can produce, but it does not stand alone. I was called to see a man in consultation on a Thursday and found that he was suffering from a severe loss of blood by the mouth, he was so blanched and weak that I dared not make any careful examination to definitely determine the source of the blood, and for immediate treatment I do not consider this very important. The history given me by his medical man was that the hæmorrhage had begun on the previous Friday; ergotin had been injected subcutaneously on Friday, on Saturday, and on Sunday; on Monday the hæmorrhage had been more profuse and, notwithstanding the injections, had reached its acme on the Wednesday evening; when I saw him on Thursday morning he had brought up about an ounce of blood; in the evening of that day he brought up a little more; after this he had no return of bleeding and steadily improved—got well, in fact, as far as my present purpose is concerned. On talking over the case we agreed to omit the ergot and substitute for it a little morphia. So far and were this all the case against ergot would seem to be almost too simple, but there is a sequel to the event which complicates matters and which was, in fact, the cause of my determination to try to get the question discussed. The sequel was this: I wrote, as is my custom, to the medical man to inquire how the case had progressed. In his reply he mentioned the hæmorrhage on the Thursday subsequent to our consultation, but confessed that he had again administered an injection of ergotin, and wound up his letter: "I trust you will not be offended, as not even you will convince me that ergot will not stop bleeding from lung or stomach if it be given sufficiently boldly." I was certainly not offended, but I was led to think very seriously of our present problem.

The points in the argument stood and stand thus: Did ergot finally check the hæmorrhage? If so, why did it not check it sooner? Did it really increase the hæmorrhage in the first two or three days? or had it no real influence whatever? In any case, was it a matter of dosage? Modern pharmacology, as represented by Dr. Lauder Brunton (and, I might say, by all other authorities, for there is no serious discrepancy between them in the physiological action of the drug), asserts of ergot that it (1) stimulates the vaso-motor centre in the medulla and any other subsidiary centres controlling blood pressure, and thereby causes an increase in this pressure; (2) depresses the motor ganglia of the heart bringing about a slower and less powerful pulsation; (3) acts on unstriped muscular fibres causing their contraction and thus a diminution in the calibre of the arterioles; (4) has no effect in producing a coagulum in a blood-vessel; (5) is a direct emmenagogue and ecbolic; and (6) markedly increases the peristalsis of the bowel. There seems to be only one point of dispute amongst experimenters—viz., whether the universally admitted increase of blood pressure is brought about by direct action of the drug on the unstriped muscle of arteries, or whether it is indirectly due to stimulation of spinal and other vaso-motor centres, a point which I venture to think is immaterial for clinical purposes.

We are now in a position, so far as ergot is concerned, to discuss the second group of medical hæmorrhages, viz., those in which except for the local damage the blood and the vessels are in general fairly healthy, and where the arrest of bleeding is the immediate object of our therapeutical measures, which by assumption cannot include surgical ligatures or forcipressure. It is obvious at once that the blood must come from (1) an artery, (2) a vein, or (3) capillaries, and it seems to me that here in a nutshell lies the possible, if not probable, explanation of the variable effects of ergot and the real scientific clue to the principles which should guide us in attempting to control a hæmorrhage which is beyond the reach of strictly topical applications. If the bleeding be arterial I cannot understand how the effect of ergot can be other than to increase it; blood pressure is increased throughout the arterial system, the damaged artery must therefore feel it equally with the others for we have not even a suggestion that ergot can exert a selective action on particular arteries; if it does thus feel it, then from the very fact of its damage and laceration it must be less capable than before of restraining the outflow of blood from its lacerated extremity—the stream may not be so large but the force of current is greater, and hence the greater liability to wash away any clot that nature has formed; it must be remembered in this connexion that it is distinctly stated that ergot has no tendency whatever by its presence to promote clotting at the end of the vessel or in the extravasated blood. If, on the other hand, the blood comes from a vein or from capillaries it is easy to understand why ergot might be expected to act beneficially, by diminishing the flow of blood through arterioles to the damaged spot. If my steps in the argument are sound, it follows that we ought to try to determine whether it is arterial, venous or capillary hæmorrhage which we are attempting to arrest before we administer ergot. This we cannot expect to determine by the intermittence and jerkiness of the flow; we must judge by other considerations gleaned from clinical study and the facts of the post-mortem room. These help us materially, and I shall say a few words about them in connexion with one or two varieties of our second group of medical hæmorrhages. Before I do so I would like to consider what are the means other than ergot at our disposal in the treatment of the condition under discussion.

Rest.—Rest, complete and absolute, bodily and mental, must occupy the place of foremost importance. The need for rest of body by lying in bed is obvious to all; it requires no argument, nor need I mention the means for obtaining it. To secure mental rest and allay the terrible fright into which the sight of copious bleeding throws the patient is even more important; it is fright that depresses vitality and tends to kill its victim. We must first of all hide our own anxiety, for patients are quick to read the faces of those attending them, and, indeed, we usually need have none, for cases of hæmorrhage are either from the first obviously and hopelessly fatal, as ruptured aneurysm, for instance, when we have no time to show anxiety, or they are rarely fatal directly from the loss of blood. As for drugs, none that I am aware of, unless it be cannabis indica, can come near to opium in efficacy for the relief of mental terror. It has no specific effect on heart or vessels when given in moderate medicinal doses, but its value is incalculable, and when we see its soporific effect stealing over the patient we may confidently assume that danger has passed.

Cold and heat.—It is the fashion to place an ice-bag on the chest or abdomen when severe bleeding has taken place, but I have not seen the slightest reason for believing that it has any effect whatever in checking the hæmorrhage. It hinders sleep and rest and constantly reminds the patient of his peril, and should therefore be avoided.

Styptics and astringents.—Of these I would mention sulphuric acid, bismuth, chalk, lead acetate, iron perchloride,

Digitized by Google

and tannic acid with the vegetable preparations that contain it, such as catechu, kino, hamamelis, &c. Any of them are extremely useful if they can be applied directly to the bleeding vessel—e.g., in gastric or intestinal hæmorrhage, but as indirect—i.e., after absorption—controllers of bleeding I believe them to be as useless or even harmful as ergot itself. Turpentine, too, must not be omitted, as from its volatility it may reach the affected area by inhalation, while iodide of potassium and purgatives are very useful adjuvants. Accepting this list as fairly representive of our armamentarium I will bring this paper to a close by a very brief sketch of the means I would propose to adopt in treating the individual cases of Group 2, mentioning the reasons deducted from post-mortem experience.

Cerebral hæmorrhage is almost invariably arterial, consequently I believe that ergot and its allies are contraindicated, rest is strongly indicated, and possibly purgatives and iodide of potassium may be given if further treatment seems desirable. The epistaxis of youth rarely requires more than the application of cold to the nose or sniffing up of powdered alum; that of age should not be too early interfered with as it forms a safety valve against intracranial arterial rupture; should it be too prolonged the local measures will again be useful, if also the patient be placed sitting upright with the feet and legs in very hot water, then plugging of the nares will be but rarely required. Pharyngeal hæmorrhage rarely requires any treatment, but the electric cautery may be applied if necessary. In hæmorrhage from the lung I believe that all our active efforts will have but little real effect. In bronchitis, pneumonia, and in the early stages of phthisis, the bleeding is rarely more than slight and will usually stop by itself if the patient be kept quiet in bed and his mind put at rest as to his danger; should it prove more profuse, in my opinion, opium must be pushed and iodide of potassium freely administered. It is in rare cases of emphysema and in the advanced cases of phthisis that we feel so anxious to employ more active measures. But post mortem we find that in such cases the bleeding is almost invariably arterial, and I must confess myself feeling very sceptical as to the value of any more active treatment which has been hitherto advocated. I feel that to bring and keep the patient well under the influence of opium with perhaps the inhalation of turpentine is as much as we can do, however distressing it may be to us to stand by and feel so helpless. I wonder whether artificial pneumothorax would be of any use.

In hæmatemesis we are more favourably situated and can adopt measures more actively and with greater hope because our drugs can reach the bleeding spot. In the young an ulceration into an artery is the almost universal causation of such trouble, and here the swallowing of ice or ice-cold water in small quantities or per contra (and better, I believe) hot water at 110° F. is very likely to be of use, while bismuth, chalk or strong solutions of tannin will very rapidly cause the formation of a plugging clot. Ergot in such cases I think worse than useless. In the hæmatemeses of older people there are two probable or possible sources for free bleeding: (1) an ulcer, chronic or malignant, in which the treatment just suggested is the best; and (2) a ruptured vein or capillary oozing from a cirrhotic liver. Here, in addition to the foregoing, ergot may perhaps be useful, though I would prefer to try free purgation.

In the hæmorrhages of typhoid fever, if profuse and accompanied by collapse and subnormal temperature, morbid anatomy has shown that an artery has always been ruptured. Such are I fear almost invariably fatal, but I believe that even here opium freely administered may save some lives. I would also give bismuth and liquid preparations of lead, though I doubt if they can reach the spot in time; ergot I feel sure must make bad worse. Slight hæmorrhage in typhoid fever I have been led to look upon as a favourable sign and one that does not require any active treatment beyond a little extra care in withholding food and seeing that the bowel is kept open. It is in all forms of uterine hæmorrhage that ergot finds its best and most correct application. On the grounds, firstly, that such hæmorrhage is almost invariably venous or capillary; secondly, that the mass of unstriped muscle in the organ is so large relatively to that in an arteriole as easily to overcome any extra arterial blood pressure.

To conclude a somewhat rambling and yet very condensed article, I would make four propositions for discussion:—1. That most cases of medical hæmorrhage cease spontaneously and are essentially not dangerous to life from loss of blood. 2. That active treatment by ice-bags and ergot frequently defeats its own purpose; if the bleeding ceases it does so in spite of treatment. 3. That where experience of morbid anatomy or the profuseness of the blood loss makes an arterial source certain ergot is distinctly contraindicated. 4. That complete rest, opium, and iodide of potassium are our most powerful and most trustworthy agents for the emergency, except in certain special cases—e.g., from stomach—where additional treatment by astringents should be applied.

Christopher-street, Finsbury-square, E.C.

CONCERNING THE ACTION OF X RAYS ON CULTIVATIONS OF TUBERCLE BACILLUS.[1]

BY FRANCIS POTT, M.D. BRUX.

THE treatment of pulmonary tuberculosis in man by means of x rays has been described by several experimentalists.[2] In the cases thus treated improvement in the state of the patient was ascribed to the curative agency of the x rays, but no sufficient proof of this action has been given, nor is there any indication of the manner in which the rays affect either the tubercle bacilli or the surrounding tissues. The experiments detailed below were undertaken with a view to ascertaining whether x rays inhibit the growth of or kill the tubercle bacillus. Preliminary experiments with x rays and glass test-tubes showed that different makes of glass were opaque to x rays in very different degrees. Soda-glass test-tubes with sensitive paper beneath them were exposed to x rays of the same intensity as those used in the subsequent experiments. Objects such as pins, keys, and chains were placed inside and underneath the test-tubes. The resulting skiagrams gave perfect pictures of those objects opaque to the rays which were inside and underneath the test-tubes, whilst the soda-glass test-tubes themselves were but faintly outlined at those points where the x rays had had to pass through the greatest thickness of glass. The slight resistance offered to x rays by thin soda-glass test-tubes was not considered to be sufficient to mar the value of the inference drawn from the following experiments.

Into twenty-five sterilised test-tubes glycerine agar-agar peptone was run and allowed to solidify in the position used for streak culture, so as to give a large flat surface. On April 21st, 1897, the agar in the tubes was sown with tubercle bacilli taken from a cultivation belonging to Dr. Arthur Ransome which had been obtained from University College Hospital and been shown to be pure and vigorous. The laboratory work was carried out by Mr. F. J. Tanner at Bournemouth. The twenty-five inoculated test-tubes were incubated at 37° C. for a month. By this time characteristic colonies of tubercle bacillus had developed in each of the tubes either as films, small colonies, or heaped-up masses. No growths other than tubercle appeared in the agar. The test-tubes were divided into sets of three and one set of four, numbered and lettered. One tube from each set was reserved as a "control," the remaining seventeen being exposed to the x rays. To ensure an equal distribution of x rays over each inoculated surface of agar the test-tubes were laid flat upon a horizontal rotary table with their closed ends converging to the centre of the table. This arrangement placed all the test-tubes well within the focal area of the Crookes's tube which hung above them, whilst it allowed the table and its load to be shifted around from time to time. Beneath the rotary table there was a space for the admission of a sensitive plate. To demonstrate that the x ray apparatus was working well at any moment during the lengthy exposure a sensitive plate was slipped into its place, exposed, and developed at once, producing a picture of the pins and metallic trifles which had been scattered amongst the test-tubes. The apparatus used for producing the x rays consisted of an induction coil giving a 5" spark, a ten volt accumulator, and several Crookes's tubes of modern pattern. These tubes were occasionally interchanged to rest them. At the

Digitized by Google

suggestion of Mr. Howlett, of Hull, damped wool was successfully used on the vacuum tubes to prevent sparking.

On May 23rd, 1897, the seventeen test-tubes containing the cultivations of tubercle bacilli were exposed to the x rays. The series of cultivations received exposures varying from half-an-hour to eleven hours. Two tubes were withdrawn from the area of the x rays at intervals of half an hour, one, two, four, six, eight, and ten hours, the remaining three tubes receiving the full exposure of eleven hours. During these eleven hours the control cultivations were taken out of the incubator and placed in a protected place at ordinary room temperature similar to that in which the experiments were carried out. At the conclusion of the experiments the whole number of cultivations was returned to the incubator.

During the first week of September, 1897, the cultivations were examined, a period of over three months having elapsed since they were exposed to the x rays. All the colonies of tubercle bacillus were found to be thriving. Differences in the rate of growth of the colonies were perceptible, both in those which had been exposed to the x rays and those which had been used as controls. These differences were only such as are usual in a series of agar cultivations of tubercle bacillus. In tube No. 16, which had been exposed to the rays for eight hours, the activity of the growth was remarkable, the colony of tubercle bacillus taking the shape of an acuminated corrugated mound with a base area somewhat larger than a threepenny piece. From this largest growth the colonies graduated downwards in size to that of a pin's head. The development of the colonies during the three months between the exposures and the final examinations was in accord with that of any large series of tubercle bacillus cultivations.

A comparison of the colonies exposed to the x rays with those used as controls showed no variation in colour, size, or manner of development which could be attributed to the different treatments which the colonies had undergone. These experiments point to the conclusion that x rays do not affect the tubercle bacillus, and lead us to believe that the improved condition of tuberculous patients who have been submitted to the influence of x rays was due to causes other than the action of the rays.

A CASE OF TETANUS SUCCESSFULLY TREATED BY TETANUS ANTITOXIN.

BY W. H. SMART, M.A., M.B. CANTAB., M.R.C.S. ENG.

A MAN, aged about forty years, came to me on July 4th, 1897, with the last phalanx of one finger crushed; the nail was removed, but the bone was uninjured. The wound was cleansed and dressed with cold water applications. All went well until July 13th, when his jaw felt stiff. During the night of the 14th he had pain in the legs, and the next day he sent for me in the afternoon, when I found him suffering from tetanic spasms of the legs occurring, I was told, about every half-hour. The jaws would open about an inch with pain, the corners of the mouth were drawn up, the eyebrows were raised, and the forehead was wrinkled transversely. There were no spasms of the arms or opisthotonos. The bowels had not been opened for four days. He was given five grains of calomel and a mixture containing two drachms of bromide of potassium and one drachm of chloral hydrate, an eighth part of which was taken every three hours. He slept during the night, avoiding spasm of the legs by keeping them drawn up, but the spasm came on again immediately any attempt was made to straighten the legs. On the 16th the jaw appeared to be a little less stiff, but the spasms were still very severe. I amputated the injured joint under chloroform and injected 10 c.c. of antitoxin at 12 mid-day. At 6 P.M. the spasms were less frequent, the jaw was still stiff, and the finger was painful. He could put the legs down and draw them up again, but it caused trembling and some stiffness. There was no spasm of the back, and the muscles of the face and forehead were in the same condition; 10 c.c. of antitoxin were injected. On the 17th I was told he had had a quiet night, but that the spasms had come on again at 10 30 A.M. The finger was dressed with chlorinated soda lotion, 10 c.c. of antitoxin were injected, and five grains of calomel were administered; the mixture to be taken as before. At 9 P.M. the patient was better, but the jaw was stiff. The spasms commenced when I came, perhaps owing to nervousness; 10 c.c. of antitoxin were injected. On the 19th he complained that he could not micturate except when out of bed, while he had pain in the right side and leg. I made him straighten and draw up the leg, which caused much trembling, but the spasms were evidently much less, and so he was reassured. On the 20th he felt better; he could open the jaws wider, and could lie with the legs stretched out. On the 26th the mouth could be opened wide; the legs were weak and inclined to get hard in the calves, but were otherwise much better. This day a carbuncle was found to be developing in the neck; this ran its normal course and the patient made a complete recovery. In all, 50 c.c. of antitoxin were injected; and though the sedatives may have assisted in the successful treatment (the bromide was continued almost until the man went to his work), I think that the symptoms were much alleviated after each dose of the serum was injected.

Polesworth, near Tamworth.

NOTE ON AN UNUSUAL ATTACHMENT OF THE FUNIS.

BY W. F. GARDENER, M.R.C.S. ENG., L.R.C.P. LOND.

ON Oct. 25th last I attended a primipara who was within a fortnight of her full time. The labour was normal and she was delivered of a small fœtus. The cord was then seen to be expanded at its fœtal attachment into a keel-shaped mass, with long diameter running from above downwards in the fœtus. The "fault" in the abdomen measured 3¼ in. in length, 2¼ in. in breadth, and stood up from the abdominal surface 1⅛ in. The mass consisted entirely of Wharton's jelly. The fœtus lived thirty-six hours.

I was unable to obtain permission to make a full post-mortem examination, but an incision into the tumour revealed beneath a layer of Wharton's jelly an inch and a quarter in depth the liver and transverse colon, so that a very large umbilical hernia would have resulted if the child had lived. I believe this to be a very uncommon condition.

Sydenham.

ARTERIAL OBSTRUCTION IN AN OLD MAN; EMBOLISM; ENDOCARDITIS; RECOVERY.

BY ERNEST MABERLY, M.R.C.S. ENG.

THE patient, a man over seventy years of age, who, with the exception of an attack of influenza, had as far as he could remember always enjoyed the best of health, came under my care on April 9th, 1897. Just two months previously he had received a severe bite from a dog on the left leg. No medical man was at first called in to the case, the patient treating the wound himself with an ointment of soap and honey and eventually applying sticking plaster. The wound appears to have partially scabbed over under this treatment, but it became very offensive and there was great congestion and swelling around it. When seen by his medical man nine days later a Goulard lotion was applied four times a day for a week. On Feb. 25th the wound was dressed with zinc ointment and bathed with warm water four times a day for a week and the leg was bandaged; the patient remained in bed most of the time. Before he left home on April 5th he began to walk about a little. On April 9th I was called in for the first time. He complained then of great constipation and flatulence and of considerable pain over the hepatic region. On examination I found the liver very congested; the tongue was white and thickly furred; the motions were clay-coloured; hardly any action of the bowels had taken place for a week. One tablespoonful of castor oil was given, and a mustard leaf was applied over the hepatic region. No action of the bowels was obtained until five grain

Digitized by Google

of calomel were administered at bedtime and half-ounce doses of sulphate of magnesium in the morning. After continuing this treatment for four days, the bowels began to act well. The motions were still hard and clay-coloured. On the 14th the patient's general condition was very little improved. He still complained of flatulence and pain in the hepatic region. The tongue was white and thickly coated, and he still had a bitter taste in the mouth. The heart and lungs were normal. There was no albumin in the urine. On the 15th the patient was confined to bed and he had a restless night. On listening to the heart a distinct soft systolic murmur could be heard at the apex. There was no thrill. The respirations were 26, the pulse was 100, and the temperature was 99·4°. There was no albumin. Large doses of quinine and iron were given with sulphate of magnesia every four hours. As to diet, milk, eggs, and beaf tea were ordered. At 6 P.M. the respirations were 28, the pulse was 96, and the temperature was 99·8°. There was no trouble with the urine, which was free from albumin. At 2 A.M. no pulse could be felt in the left wrist. Hot fomentations were applied to the forearm. The nails were very blue. On the 16th, at 11 A.M., the respirations were 18, the pulse was 84, and the temperature was 98·5°. The radial left pulse was scarcely perceptible. On listening to the heart a very loud systolic murmur could be heard. The whole of the left forearm was painful; it was very blue and congested. The hot fomentations were still continued and at 2 P.M. the pulse of the left radial artery was stronger. On the 17th, at 10 P.M., the pulse of the same vessel was very thready. The respirations were 28. The mitral murmur had gone. On the 19th the forearm was resuming its natural colour. There had been a great deal of pain in the left leg all night. Hot fomentations were ordered. On the 20th, at 12 noon, the pulse was 78 and the respirations were 24. The patient still complained of great pain in the left knee-joint. There were no cardiac murmurs. No pulse could be felt in the foot. The hot fomentations were continued. On the 21st, at 10 A.M., the pulse was 72, the respirations were 18, and the temperature was 98·4°. The pulse returned in the foot. There was no pain. The fomentations were discontinued. From this date up to April 29th the patient made an uninterrupted recovery.

Throughout the illness, although there was great constipation, the patient perspired freely, and this no doubt accounted for the comparatively low temperature. Stimulants were freely given during the illness. When convalescent the patient went to the seaside for a couple of months. Swelling of the foot and leg continued for some time, but this was reduced by careful bandaging and massage and at the end of two months he wrote to me saying that he was well enough to return to his ordinary duties.

Eversley, Hants.

MANCHESTER CHILDREN'S HOSPITAL.—On Nov. 13th Sir William Agnew formally opened a new convalescent home which he has built and equipped and presented to the Manchester Children's Hospital. The home will accommodate twenty-five patients, and it is expected that the resident officials will be a matron, two nurses, and two servants. It stands about a mile from St. Anne's railway station on the road to Blackpool and has a fine view of the sea. Mr. J. Francis Richardson, chairman of the board of governors, presided at the ceremony and received the deed of gift from Sir William Agnew who said that there was no incident in his career that he would refer to with greater pleasure than the transaction of that day.

LUXOR HOSPITAL FOR THE NATIVES OF UPPER EGYPT.—An appeal is being made by Mr. Thomas Cook for contributions towards the support of this hospital which was opened by His Excellency the late Khedive at the commencement of the year 1891. In order to show the necessity for such an institution it is stated that on the day of opening fifty natives were waiting for the medical officer's attention and up to the spring of the present year medical and surgical treatment was afforded to 25,820 cases, for whom about 493 operations were performed, and no less than 28 781 out-patients had been relieved, of whom about 5178 were females. During last year 327 in-patients were treated, the daily average of in-patients being seventeen. 6240 diets were issued and 107 operations performed. Each ward is isolated from the others, and there are twenty-six beds available for in-patients.

ST. MARY'S HOSPITAL.

A CASE OF ANEURYSM OF THE ABDOMINAL AORTA, WITH SYMPTOMS OF RENAL COLIC; NECROPSY.

(Under the care of Dr. CHEADLE.)

THE following case derives its interest from the great similarity of the symptoms in the early stages to those of renal calculus, and later to those of perinephritic abscess. Aneurysms of the abdominal aorta may attain no inconsiderable size without giving rise to any painful symptom, but this is only possible when the aneurysm arises from the anterior aspect of the vessel, for when the aneurysm grows backwards from the artery and presses on and erodes the vertebræ pain, violent and lancinating, is generally present. For the notes of the case we are indebted to Dr. F. John Poynton, Medical Registrar, and Dr. Arnold F. Bill, Demonstrator of Pathology.

The patient, a man aged forty years, was admitted to St. Mary's Hospital on June 2nd, 1897, on account of paroxysmal pain in the abdomen shooting down to the left testicle. This had occurred in paroxysms sometimes once a week and sometimes once a month for the last four years, but during the last six weeks they had become more frequent and more severe; he had, in addition, suffered from headache, hæmaturia, and hæmoptysis. He was of middle height and emaciated, and his face was pale and worn with pain. The temperature was 101° F., the pulse was 84, and the respiration was 20. He said that the pain was situated on the left side of the abdomen and in the left lumbar region, and that when a paroxysm came on it shot down to the left testicle and was so severe that he was compelled to hold his scrotum with his hand. He had never vomited with the pain nor was it increased on movement. Examination of the abdomen showed slight retraction of the parietes with marked hyperæsthesia over the left kidney, both in front and behind, but revealed nothing further. The bowels were constipated. The urine contained a trace of albumin but no blood. The cardiac impulse was forcible and was felt in the fifth space just outside the nipple. No adventitious sounds were heard. The lungs were apparently normal. On June 4th, at 2 A.M., after micturition, a severe paroxysm of pain occurred, commencing in the left testicle and passing up the left side of the abdomen, without vomiting or blood in the urine. A dull, aching pain remained after the attack. Several more severe attacks of pain occurred during the week, but on June 11th the symptoms changed. There was violent heaving over the left side of the chest, pulsation was present in the epigastrium, and a loud systolic bruit was heard over the upper part of the abdominal aorta. The twelfth rib was moved by pulsation in the left flank and over it the heart-sounds could be counted. There was an impaired note in the left lateral region of the chest reaching to the tenth rib. On the 25th the patient felt pain down the front of the left leg to the foot and the pulsation in the epigastrium had extended to the right of the middle line. On July 5th he was blanched. The dulness in the left side of the thorax had reached to midway between the spine and angle of the scapula. At the upper limit there was ægophony and over the dull area the breath sounds were faint. There was fulness in the left renal region, which was very tender on pressure and gave a dull note on percussion. Since June 25th the temperature had varied between 99° and 100°. On July 8th the patient became unconscious and died. During the last few days the bruit in the epigastrium had disappeared.

Necropsy.—A post-mortem examination was made by Dr. Poynton, and a detailed dissection by Dr. Bill after removal of the aneurysm and surrounding structures from the body. The body was found to be much emaciated. In

Digitized by Google

the left pleural cavity there was a considerable quantity of clear fluid. Centrally and to the left the diaphragm bulged upwards displacing the heart. The descending colon was remarkably small, and was superficial to a large purple sac, which occupied the left hypochondriac, lumbar, and iliac regions. Removal of the stomach, spleen, pancreas, and intestines exposed a large aneurysm of the lowest part of the thoracic and upper part of the abdominal aorta. The upper limit was at the level of the disc between the ninth and tenth dorsal vertebræ and the lower at the lower edge of the first lumbar vertebræ; the upper part of the aneurysm was covered by the upward displaced diaphragm. The superior mesenteric artery came off about half an inch above the lower limit, and the cœliac axis about an inch higher. There was no interference with the circulation in these vessels. The posterior boundary was formed by the partially eroded vertebræ of the tenth, eleventh, and twelfth dorsal and the first lumbar vertebræ. The twelfth rib on the left side was also eroded for about an inch. There were masses of clot to the right and left outside the true sac of the aneurysm of two different dates. The earlier lay to the right and behind the aorta, and was much decolourised, and where it touched the aorta partly organised. This was continuous behind the aorta, with a second mass consisting of currant jelly clot and liquid blood, which lay to the left, forming the purple sac above mentioned. The boundaries of this second mass were the peritoneum with the descending colon in front, the posterior wall of the abdomen behind, the left suprarenal and kidney with the left ilium externally, and the vertebral column, mesenteric attachments, and third part of the duodenum toward the middle line. Below these were prolongations under Poupart's ligament and into the left spermatic cord. The aneurysm was compressed between these masses into a cavity whose horizontal section was roughly S-shaped. The only opening in the neighbourhood of the old clot was in the posterior wall of the aneurysm, in its lower part, slightly to the left of the middle line, but the whole of the left wall was very friable. No trace of the sympathetic could be detected around the aneurysm or in the clot. The eleventh and twelth dorsal and first lumbar nerves were exposed, but there was no evidence of gross lesion to their structures.

BURTON-ON-TRENT INFIRMARY.

A CASE OF CÆSAREAN SECTION.

(Under the care of Mr. P. B. MASON.)

THE mortality after Cæsarean section varies greatly in different sets of statistics, and this may be in part at least attributable to the fact that while some gynæcologists employ the method before the commencement of labour others use it only after determined attempts have been made to extract the child *per vias naturales*. When Cæsarean section is undertaken before or shortly after the commencement of labour, with full antiseptic precautions and with adequate assistance, the mortality should be very low—not exceeding 5 per cent.—and the results of the operation are then comparable with those following alternative methods of treatment. For the notes of the case we are indebted to Dr. J. P. Sparks, house surgeon.

A woman, forty years of age, was admitted to the Burton Infirmary on Aug. 9th, 1897, suffering from cancer of the vagina and the os uteri, complicated by pregnancy. The patient stated that for about a year she had suffered from repeated losses of blood at intermittent periods, and on being examined by her medical attendant she had been found to be suffering from an epithelioma in the region of the urethra which extended up the anterior vaginal wall and involved the anterior lip of the os uteri. Becoming pregnant soon afterwards, she was seen by Mr. Mason in consultation and it was decided to wait till labour came on and then to perform Cæsarean section. Labour commenced on Sept. 26th, and the operation was performed in the afternoon by Mr. Mason. A long incision was made from a point one inch above the umbilicus to the pubes, and the uterus immediately presented in the wound. The placental site having been ascertained to be on the posterior wall, the uterus was opened by an incision about five inches long commencing at the fundus. The uterus was well pressed forward and the broad ligaments were compressed on each side by assistants. The child and placenta were then rapidly extracted, the uterus was closed with deep and superficial sutures of silk, and the wound of the abdominal wall was sewn up. The operation lasted one and a quarter hours and the patient did not lose more than four ounces of blood. Convalescence was uninterrupted and the patient left the hospital on Oct. 17th. The child is alive and well.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

A CASE OF HÆMATOSALPINX.

(Under the care of Dr. THOMAS OLIVER.)

THOUGH it is extremely probable that a large number of cases that have been described as examples of hæmatosalpinx have really been instances of tubal pregnancy, yet there can be no doubt that cases do occur, as in the one recorded below, in which the collection of blood in the Fallopian tube is in no way connected with impregnation. It is true that there is some difficulty in accounting for the accumulation of blood in the tube though it is very probable that during menstruation there is effusion of blood from the mucous membrane of the tube as well as from the wall of the uterus, and possibly some cases are explicable as due to reflux from the uterus. In practically all cases of hæmatosalpinx the blood remains fluid for a very long time.

An unmarried woman, aged twenty-one years, who resided at home, was admitted into the Royal Infirmary, Newcastle-upon-Tyne, under the care of Dr. Oliver, on May 25th, 1897, complaining of severe pain in the right iliac region and lower half of the abdomen of four years' duration. There was nothing in her family or previous history that calls for comment beyond the fact that she first menstruated at the age of sixteen years, that she had since been very irregular, occasionally passing six or seven months without becoming unwell, and that when she did menstruate the flow continued for four or five days, but was scanty and always very painful. She remembered well her first menstruation, for it was attended by much pain, which radiated outwards towards the right iliac region and down the right thigh, lasting for several hours. She was unable to pass urine. With each recurrence of menstruation there had been both difficult and painful micturition. So severe was the dysmenorrhœa that she was completely unfitted at her menstrual periods for domestic work. During her intermenstrual periods she had frequently noticed, if she lifted anything heavy or strained herself in any way, that the abdominal pain was intensified.

The patient was sparely built, but when free from pain she took her food well and was apparently of a cheerful disposition. On examination the heart and lungs were found to be healthy. The abdomen was somewhat retracted, but with gentle palpation there could be felt a hard and somewhat resistant swelling situated a little above, and to the right of, the pubes and extending for a short distance outwards along Poupart's ligament. It was painful on pressure. Examining her under chloroform Dr. Oliver found that the vagina was small and narrow, the hymen intact, the cervix uteri small, and that the sound readily passed into the uterus in a distinctly left direction. Lying to the right of the uterus, occupying the whole of the *cul-de-sac* and projecting into the vagina, could be felt a rounded, smooth, tense swelling which gave a distinct sense of fluctuation when caught between the hand placed on the abdomen and the fingers in the vagina. The cyst was not very moveable; it lay close up to the uterus, but was evidently not a part of it. Dr. Oliver considered it to be a small ovarian cyst or a distended tube. On June 11th his surgical colleague, Mr. Williamson, opened the abdomen, and after separating the omentum, which at places was adherent to the wall of the abdomen, he found in the right iliac region close to the uterus a large elongated mass which was very adherent. The adhesions were separated, but as some of them were very vascular they had to be ligatured. The cyst, which proved to be a large Fallopian tube, was ligatured close to the uterus and divided. Several adhesions around the ovary were similarly dealt with and the ovary itself was removed. The Fallopian tube thus removed was in shape and size not unlike an ordinary sheep's horn; it tapered to a fine point towards its uterine extremity and was round and blunted at its fimbriated end. It was greatly distended and on section

Digitized by Google

was found to be filled with blood, grumous and chocolate in colour, not coagulated, and exactly resembling the fluid that escapes from the uterus in a case of suppressed menstruation when an imperforate hymen is incised. Careful examination of the interior of the tube and of its contained blood failed to reveal anything of the nature of old or recent clot, embryo, membranes, or anything suggesting the probability of the case being one of tubal gestation. The walls of the Fallopian tube were thickened, hard, and resistant, while the mucous membrane, instead of being thinned and atrophied as might have been expected, was swollen.

Remarks by Dr. OLIVER.—I am inclined to agree with Cullingworth[1] both when he says that the majority of cases of hæmatosalpinx are tubal pregnancies and also that there is a considerable number of cases where the Fallopian tube is found distended with blood, forming a sausage-shaped tumour, and where the evidence of it having originated as a tubal pregnancy is inconclusive. The most careful search frequently fails to detect an embryo, chorionic villi, or any other indisputable product of conception. In the tube removed from my patient there is not the slightest indication of there having been a tubal pregnancy. There was apparently a congenital narrowing of its uterine end which had caused retention, and as the character of the fluid was exactly the same as that observed in retained menses it seems to me that at her periods the girl had also menstruated into her right Fallopian tube, and the reason why she had been able to continue doing this for such a length of time was the irregularity and lengthened absence of the flow. I offer no opinion as to how far Bandl is correct when he says that normally the uterine end of the Fallopian tube is patulous during menstruation. If the statement is really one of fact then abnormal constriction would favour hæmatosalpinx. The distal extremity of the tube in my patient was rounded, occluded, and adherent. Formerly patent it is more than likely that blood escaped from the tube by this orifice and set up peritonitis, hence the explanation of the extensive adhesions of this end of the tube and the ovary. I admit, with Lawson Tait, Bandl, and others, that during menstruation blood oozes from the tubal mucous membrane and finds its way into the uterus. If it cannot escape as in the case just recorded on account of congenital narrowing of the uterine end and the distal extremity has become occluded, the blood must accumulate in and distend the tube, causing considerable pain owing to peristaltic contraction of the tube and stretching of the peritubal inflammatory adhesions. The physical signs of hæmatosalpinx can scarcely be differentiated from those of pyosalpinx. It is only after abdominal exploration and section of the tube that an accurate diagnosis in most cases can be made, but if the uterine end of the Fallopian tube is not completely occluded, then just as in similar cases of pyosalpinx where the physician is aided in his diagnosis by the history of sudden discharges of quantities of fœtid pus shortly after menstruation, so in hæmatosalpinx the sudden discharge of a quantity of disintegrated blood after a menstrual period would suggest, but would not be absolutely conclusive of, the existence of hæmatosalpinx. Where hæmatosalpinx is suspected and the tube is enlarged and adherent, where the patient is the subject of severe and recurrent pain, medicinal treatment can be of no avail beyond being palliative. The proper treatment is abdominal section and removal of the occluded tube.

[1] THE LANCET, June 19th, 1897.

ROYAL INSTITUTION.—Professor Oliver Lodge, F.R.S., will deliver the first of a course of six Christmas lectures (specially adapted to young people) on the Principles of the Electric Telegraph at the Royal Institution on Dec. 28th. The remaining lectures will be given on Dec. 30th, 1897, and Jan. 1st, 4th, 6th, and 8th, 1898.

ADULTERATION PROSECUTIONS.—At Pontypridd Police Court on Nov. 10th a grocer was fined £2, including costs, for selling half a pint of cotton seed oil as olive oil.—At Exeter Police Court on Nov. 12th a dairyman was fined £12, including costs, for selling adulterated milk. The inspector found three cans in the man's cart, one of which contained scalded milk, another raw milk, and the third water with a little milk added. Two samples of milk purchased by a customer proved to be diluted, one having 13 per cent. and the other 16 per cent. of added water.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Spontaneous Fracture of Gall stones.—Congenital Malformations of the Heart and Thoracic Veins.—Developmental Malformation in Fishes.—Intussusception of the Vermiform Process.—Exhibition of Specimens.

A MEETING of this society was held on Nov. 16th, the President Dr. PAYNE, being in the chair.

Dr. ROLLESTON exhibited a specimen of Spontaneous Fracture of a Gall-stone in the Gall-bladder. The specimen was taken from the gall-bladder of a woman, aged forty-six years, who died from spheroidal-celled carcinoma of the gall-bladder. The gall-bladder was enlarged and contained mucus unstained by bile, numerous small (cholesterin) calculi, and three larger calculi. The largest resembled in size and shape the terminal phalanx of the thumb, the two ends appearing to have been broken across; of the other two larger calculi one was smooth and like a pebble, the other showed a surface which might have fitted one of the ends of the largest calculi, but owing to attrition the surfaces did not fit accurately. Fracture had evidently taken place a considerable time before death. There was no history either of a blow or of violent contractions during biliary colic. The cause of spontaneous fracture of gall-stones might be explained on the same lines as spontaneous fracture of vesical calculi, as expounded by Dr. Ord, Dr. Plowright, and Mr. Hurry Fenwick. Dr. Ord first suggested expansion of the nucleus which led to bursting of the calculus like a bomb; in another case he found it due to mycelial growth passing between the layers and levering off the outer zones. Naunyn pointed out that biliary calculi are normally penetrated by cholesterin which re-crystallises inside the calculi and Chauffard showed that calculi may be invaded by micro-organisms. The possibility of cancerous invasion of the gall-bladder as a direct cause was considered but hardly appeared probable. In a case of spontaneous fracture of a gall-stone recorded by the late Dr. Hadden there was no growth in the liver or gall-bladder.

Dr. JAMES CALVERT also showed a specimen of Spontaneous Fracture of a Gall-stone taken from a man who died at the age of sixty-seven years from carcinoma of the prostate with secondary growths in the liver. There were no symptoms of the presence of gall-stones during life. The gall-bladder was not enlarged but its walls were thickened by chronic inflammation and it was full of broken gall-stones. The gall-bladder contained no bile or even mucus. With hardly an exception the gall-stones were in fragments, showing yellow crusts of cholesterin, and they were drier than usual. The fractures had evidently occurred at different times, the edges of some fragments being sharp, while those of others were worn smooth. Some of the stones showed fissures preliminary to fracture. Dr. Calvert thought that the fractures had been brought about by cicatricial contraction of the inflamed gall-bladder and that the stones had probably become unusually brittle owing to the absence of bile and mucus from the gall-bladder just as they become brittle and are apt to crack spontaneously when they are allowed to dry in the air.—Dr. WILLIAM HUNTER said that he had no personal experience of these cases. He asked whether the breaking up of the calculi might have been caused by the scaling off of the superficial layers of cholesterin.—Mr. SHATTOCK said that the view of Dr. Ord appeared to be correct that breaking down of a calculus was due to alteration of the colloid material distributed throughout the substance of the stone. He asked whether in Dr. Rolleston's case there was any admission of bile into the gall-bladder. If bile were excluded, and mucus, which had a different specific gravity, alone bathed the stone, alterations would be produced in the colloid material which would favour disintegration of the calculus. He did not agree with Dr. Plowright's views which had been quoted that the fissures were caused by the invasion of salts. He thought that the fissures occurred first and that the salts were deposited in them afterwards.—Dr. VOELCKER did not feel convinced that the specimen shown by Dr. Rolleston was actually one of spontaneous fracture. There was no satisfactory explanation of the frequent occurrence of many small calculi, sometimes faceted, sometimes not, along with one or two large ones;

Digitized by Google

but unless they were definitely fractured and the surfaces could be shown to fit he would hesitate to put them down to spontaneous fracture. There was an undoubted specimen of spontaneous fracture in the Museum of the Middlesex Hospital. The portions were passed per rectum, having evidently escaped from the gall-bladder by ulceration into the large intestine. When fitted together they formed a perfect cast of the gall-bladder.—Dr. ROLLESTON, in reply, said that in his case the gall-bladder contained mucus but no bile. He thought that there could be no doubt that there had been fracture.

Dr. FREYBERGER read notes and exhibited specimens and drawings from a boy, eleven months old, in whom the following Congenital Anomalies of the Heart and Thoracic Veins were present: (1) two descending venæ cavæ each with an azygos vein of its own, the left cava entering the coronary sinus; (2) congenital stenosis of the pulmonary artery; (3) absence of the membranous part of the intraventricular septum; (4) origin of the aorta from both ventricles; (5) patent foramen ovale; and (6) patent ductus arteriosus. Death occurred from meningitis. There was no trace of any fœtal endocarditis and there was no clubbing of the fingers. The lungs were well developed. The following conclusions must be drawn: 1. The absence of any signs of fœtal endocarditis shows that the malformation of the heart is due to an arrest of development at some time during the second month of fœtal life, a view which is further supported by the concomitant anomaly of the thoracic veins. 2. The full development of the lungs and the slight cyanosis during life shows that there must have been a sufficient circulation of blood in them although the pulmonary orifice is almost impassable. 3. This circulation of blood has taken place through the stenosed pulmonary orifice, the Botallian duct, and the anterior and posterior bronchial arteries. These arteries form more or less wide anastomoses with the capillaries of the pulmonary artery, and might in this case have helped to supplement the pulmonary circulation.—The PRESIDENT remarked that one of the commonest of all abnormalities of the heart was the perforate septum ventriculorum. It was just possible that this was known to the early anatomists such as Galen who believed that the blood in adults passed through the septum ventriculorum to get from the right side of the heart to the left.

Dr. FREYBERGER also exhibited a specimen of Rupture of an Aortic Aneurysm into the pericardial sac. The patient, a man aged forty-two years, was admitted in a moribund state into the Great Northern Central Hospital on Oct 27th, 1897. He had never been ill before, was a total abstainer, and had never had syphilis. He had been shovelling coal when he gave a cry and fainted. He was at once taken to the hospital where he arrived perfectly unconscious, deathly pale, and covered with clammy perspiration. His respiration was frequent and shallow, the heart sounds were feeble, and the pulse was not perceptible. Death occurred an hour after the accident. At the necropsy the pericardium was found to contain ten ounces of fluid blood and eleven ounces of dark blood-clot, completely concealing the heart. The heart was small and flabby; there was much sub-pericardial fat. The ventricles were empty; there were patches of atheroma on the aortic and mitral valves; the valves were competent. Above the left coronary orifice there was an irregular oval opening in the wall of the aorta three-quarters of an inch by half an inch which lead into an aneurysmal sac of the size of a walnut. The sac was situated at the insertion of the aorta into the left ventricle and was adherent to the left auricle. The hæmorrhage had occurred through an irregular opening in the sac of the aneurysm at a place near this adhesion. All the other organs were natural.

Mr. C. G. SELIGMANN showed a specimen of Arrest of Development in the Upper Jaw of a Pike. Instead of being almost as long as the lower, and slightly concave upwards, the upper jaw was short and markedly convex from the crown of the head to the tip of the nose. The ethmo-vomerine plate, although somewhat shortened and bent downwards, was well formed for the greater part of its length and bore the usual array of teeth. The maxillæ were normal, but the pre-maxillæ, which should bear the whole series of lateral teeth, were small and bore only a few diminutive teeth. The prefrontal bones were also much reduced in size. There were similar specimens in the Museum of the Royal College of Surgeons of England. They were examples of different stages of the same defect, arrest of development of the elements corresponding to the fronto-nasal process. The slighter cases, such as that exhibited, probably correspond to the defective development of the pre-maxillæ which in man gives rise to hare-lip.

Mr. SELIGMANN also showed a specimen of Supernumerary Fin in a Trout caught in the River Itchen. The fin was composed of ten soft fin rays, and was situated in the mid-dorsal line, just behind the head, and 5 cm. in front of the dorsal fin. All the other fins were present and normal. Mr. Seligmann described the development of the fin in other fishes, and thought it probable that in the specimen shown the supernumerary fin represented an anterior part of an originally longer dorsal fin and that the extra fin was homologous with the spiny rays of the gastrosteidæ, the tentacles of lophius, and the anterior spiny fin of many other fishes.

Mr. HERBERT WATERHOUSE showed a specimen of Intussusception of the Vermiform Process. Several days before the child was admitted to the Victoria Hospital for Children signs of intussusception were present and the child was examined under an anæsthetic. While being manipulated the tumour suddenly disappeared. A few days after the symptoms again became urgent, and an enema having failed to give relief Mr. Waterhouse performed laparotomy. He at once came on an intussusception, which was easily reduced, and then found another which was in the region of the cæcum. Part of it was reduced with some difficulty, but there was a residue which could not be replaced which proved to be the everted appendix. The cæcum was excised and anastomosis effected with the aid of Murphy's button but the child did not recover from the shock. At the necropsy the appendix was found everted into the lumen of the cæcum, only five-eighths of an inch being left outside. It formed a mass the size of a cherry, which could not be reduced. It was not cut into, but he passed a needle through it and could not find any evidence of a concretion.—Mr. D'ARCY POWER said that in the last operation which he had performed for intussusception he had found on unravelling the bowel a commencing invagination of the base of the appendix, which was probably antecedent in his case and in that under the care of Mr. Waterhouse to the invagination of the ileum.

The following card specimens were exhibited:—

Mr. P. FURNIVALL: Symmetrical Rodent Ulcer of the Face.

Dr. ROLLESTON: Rodent Ulcer of the Umbilicus.

Mr. W. G. SPENCER: Squamous Epithelial Cancer of the Upper Jaw from a young man twenty years of age.

Mr. T. STRANGEWAYS PIGG: (1) Symmetrical Rodent Ulcer from the Groins; and (2) Lymphatic Glands and Infarct of the Spleen from a case of Plague.

Dr. HECTOR MACKENZIE: (1) Cystic Kidney from a man fifty-two years of age; and (2) Perforating Ulcer at the Pylorus, associated with great hypertrophy of the gastric wall.

Dr. VOELCKER: Chronic Interstitial Nephritis with formation of cysts.

Mr. CECIL BEADLES: (1) Ulcerative Colitis; and (2) Fibrous Laminæ on the Pleura.

Dr. W. HUNTER: Gumma of the Liver.

CLINICAL SOCIETY OF LONDON.

Calot's Operation for the Immediate Reduction of Angular Deformity of the Spine.

A MEETING of this society was held on Nov. 12th, the President, Mr. LANGTON, being in the chair.

Mr. A. H. TUBBY and Mr. ROBERT JONES (Liverpool) read a paper communicating the results of a first series of twenty-five cases of Angular Curvature of the Spine treated by Immediate Reduction after Calot's method. Although at first they were sceptical as to the safety of the operation, since it seemed to contravene all received ideas about the treatment of the condition, the results witnessed by them at the cliniques of Calot and Rédard induced them to give the method a trial. The present series contained the cases operated on by them up to the end of September, 1897. They said that the examination of many cases under anæsthetics had led them to believe that cases of angular deformity could be grouped into three classes. 1 Those in which little or no ankylosis has taken place and reduction can be effected with great ease. These are most commonly met with in the young. 2. Those in which more or less union has taken place. These require

Digitized by Google

extension to be maintained for several minutes with firm pressure on the curvature. 3. Those in which firm bony ankylosis has taken place. Interference with the cases in the last group was unjustifiable, but those in the first two were suitable for immediate reduction. They considered that the procedure had the following advantages: the greater ease of fixing the spine in a good position after it had been straightened; the avoidance of deformity of the chest with compression of the thoracic and abdominal viscera; and lastly, æsthetic reasons as to appearance. The probable dangers were discussed, and it was shown that although paralysis would naturally be dreaded as a result it had not occurred in any of their cases, but that, on the contrary, five of their cases affected with varying degrees of paralysis had commenced to recover immediately after the operation and had steadily improved. Another risk was the dissemination of tubercle, and this they thought was less likely to occur than in such operations as erasion and excision of the large joints, in which more or less healthy bony surfaces were apt to be inoculated with tubercle. In no case did the formation of an abscess follow the operation. As to the permanency of the reduction, they stated that in some it remained permanent, but that in others slight relapse took place requiring a repetition of the operation. The duration of the necessary after-treatment was from two to three years, a greater time than had been recommended by French surgeons. The details of the operation were described and illustrated by lantern slides. Extension might be applied by having several assistants to hold the child face downwards while extension was made from the legs and the head, which latter might be grasped by the head-piece of Sayre's suspension apparatus. It was very necessary that the extension should be equable and not jerky. Mr. Tubby and Mr. Jones had devised a form of rack which acted very well but took some time to adjust. After the operation the patient was placed on a modified double Thomas's splint with a very full curve, so as to over-extend the spine. This was preferable to the cumbersome plaster cuirass which was recommended by Calot. The cases operated on had not been specially selected, all cases being taken unless there were strong reasons to the contrary. In the series of twenty-five cases operated on there had been one death, six days after the operation. Death occurred unexpectedly with acute abdominal symptoms, but at the necropsy these symptoms were not satisfactorily accounted for, nothing being found in the abdomen abnormal except tuberculous lymphatic glands. Of the twenty-five cases nine were males and sixteen females, and their ages ranged from eighteen months to twenty-two years. The deformity had been present from six months to six years. Five had paralysis, and all improved, apparently as a direct result of the operation. One had a discharging sinus in the groin at the time of the operation. As to the position of the curves, two were cervico-dorsal, eighteen were dorsal, and five were dorso-lumbar. Ten cases were reduced at the first sitting and fifteen partially. Of the ten complete reductions two remained so for from three to four months afterwards, and the slight recurrence which took place in eight was speedily overcome by a second operation. Of the fifteen partial reductions two required two subsequent operations and one three. The remainder were greatly improved, and the prominences were reduced to about one-third or less of their original size. The cases which Mr. Tubby and Mr. Jones deemed unsuitable for the method of treatment were those where the disease was of long standing, where ankylosis had occurred, and where there was considerable deformity of the chest; those in which active tuberculous disease was present elsewhere; and those in which abscesses had occurred. The cases which were held to be suitable were (1) those occurring in young subjects in which the angle was a changing one, the disease of short duration, and firm ankylosis absent; (2) those in which the disease was locally active; (3) those in which no visceral complications were present; and (4) cases of paraplegia unrelieved by ordinary treatment, as a more reasonable proceeding than laminectomy, which often fails to relieve the pressure point. With the reservations mentioned Mr. Tubby and Mr. Jones thought that an angle which is increasing more rapidly than the growth rate will explain can with tolerable facility and without undue risk be rectified. They felt, however, that the method was one which, if care was not taken to select suitable cases, might lead to disastrous results.

Dr. CALOT (Berck-sur-Mer), speaking in French, said that he did not admit any other ground for intervention in cases of Pott's disease than that of correcting the deformity. To endeavour to treat the paralysis or abscess by ordinary surgical measures meant the transforming of a "closed" disease into an open one, changing it, in other words, from a condition in which there are 95 per cent. of cures into one in which the mortality is very high. The attitude of a prudent surgeon should be the same as in overcoming deformities in the hip or knee. Dr. Calot said that in his first series of 37 cases there was not a single instance of any untoward symptom after the operation. Rédard read notes of 32 cases without an accident before the Moscow Congress; Hoffe, of Strassburg, 36 without any mishap; and Jones, of Liverpool, has now performed the operation 60 times with only 1 death. On the other hand, Brun and Jenesco lost a child under chloroform, Malherbe 1 from respiratory embarrassment, and from the same cause Bilhaut lost 3 out of 50 cases, and Dr. Calot himself 2 out of close upon 300 cases. Out of 600 cases of which notes had been forwarded to him by various surgeons paralysis followed the operation in 3. But it must be borne in mind that in Pott's disease paralytic complications occur in about one-fifth of the cases. As a set-off against this eight cases of paraplegia existing at the time of the operation were relieved by it. Dr. Calot considered that these results were as favourable as the results of any other surgical operation had been at the time of its introduction, and no doubt future statistics would show even better results, as it seemed likely that it would be possible to dispense with an anæsthetic, thus materially diminishing the risks. The cases must be selected. Unsuitable cases are cachectic children, those with active chest mischief, those with spinal abscesses or sinuses, and those with a hump of long standing which does not yield to a traction of from 50 to 80 kilogrammes. Dr. Calot then passed on to consider the treatment of long-standing cases in which there was ankylosed deformity. Scharr had taught twenty-three years ago that consolidation in cases of Pott's disease left to themselves takes place either by simple union of the posterior parts of the column (false ankylosis), or by union of the healthy bodies of the vertebræ as well as of the posterior parts (true ankylosis). It may occasionally happen that union of the bodies takes place without union of the posterior parts, but this must be exceptional. As a rule the resistance to reduction in the more severe cases is in the posterior bony union. In such as are reduced by strong traction (80 kilogrammes) a large number of bony bands are broken through, as shown by the crepitus, which is sometimes felt during reduction. He rarely used greater traction than 80 kilogrammes, but had done so in exceptional cases, such as that of a Swedish girl aged thirteen years. He was convinced that it was possible, however, to reduce even old-standing curvatures, but he thought that it was better to lay the bony adhesions bare before breaking them down. If they were only posterior they could be broken down by a trifling operation. If bony union also existed anteriorly the surgeon might begin by breaking down the posterior adhesions, and then, except in persons over twenty, traction alone would suffice to reduce the deformity. Should this prove fruitless he would know that true bony ankylosis had taken place. Even then, however, he thought that the resources of surgery were not exhausted. It would still be possible to break down these anterior adhesions by a second operation, attacking them laterally, taking care not to enter the spinal canal. It would suffice to weaken the resistance of the anterior callus, which would then yield to firm manipulation. In very old curvatures interference was perhaps undesirable. The formation of abscess, generalised tuberculosis, and meningitis which would be expected to follow this treatment, Dr. Calot considered less to be feared than after operations on tuberculous knees. In the latter operation it is impossible to avoid breaking down bony processes themselves infiltrated with tubercle, whereas in the extension of the spine the anterior segments are raised without rupture of the trabeculæ and the pressure resulting from the replacement of the posterior parts bears on bony structures which are themselves quite healthy. Out of upwards of 300 cases he had only seen four instances of tuberculous broncho-pneumonia or meningitis occurring in the six months following reduction. Since tuberculous processes favour destruction rather than repair it would be thought that relapse would be certain to occur, but experience showed that the objection had no practical value, and that the spine undergoes

Digitized by Google

consolidation after reduction just as it does when left to itself. Skiagraphs show clearly that union in some cases takes place by anterior union, and this may give rise to some protuberance. Or, as Dr. Calot had observed twice after death and in ten instances in the living subject, it may take place by posterior union. In four out of twelve cases this has appeared to be sufficient, but in seven it was insufficient in the sense that an insufficient number of vertebræ were joined together. In default of union it is always in the power of the surgeon to bring it about artificially by denuding the laminæ at the parts where they are in contact, and uniting the periosteum over the site of the proposed junction. When dealing with a very pronounced curvature the reduction may be attempted in stages at several weeks' interval, being careful not to wait so long that firm union has occurred in a partially corrected attitude. His rule was to provoke union between at least two vertebræ more than appear necessary to ensure the stability of the union. He had performed this operation on ten occasions, and his cases showed that posterior union alone was sufficient to maintain the proper position of the vertebral column. Dr. Calot described the plaster apparatus which he employs. It includes the whole of the trunk, along with the neck, the base of the head, chin, and occiput. In applying the cervical part he makes use of a suspension apparatus. The application of the plaster casing does not take more than a few minutes. At the Moscow Congress Dr. Calot reduced the deformity and applied the plaster support in six cases without occupying more than seventy-five minutes. If the child is not inconvenienced, and there is no rise of temperature, the jacket is left on for from three to five months, and it may be renewed several times. It may be necessary to make a window in the case opposite the curvature in order to dress any sore that may have formed there. The duration of the treatment when in an active stage is that of the disease itself—several years; but otherwise the treatment need not take more than three or four months. Should any recurrence of the deformity take place he would advise artificial union and, indeed, was almost disposed to recommend this procedure as a routine or prophylactic measure.

Mr. R. W. MURRAY (Liverpool) said that since August, 1897, he had operated on fourteen patients whose ages varied from two and a half to nine years. The duration of the deformity varied from a few months to four years. Most were in good general health, but one had a small psoas abscess and another was paraplegic. Three had the curvature in the cervical region, nine in the dorsal, and two in the lumbar. The operations were uneventful except in the case of the paraplegic child, whose breathing was seriously embarrassed for a time. His paralysis now, two months later, is improving. The immediate results, on the whole, have been satisfactory, but in one of the cervical cases weakness of the lower limbs has supervened, probably owing to the operation, and in one of the first cases operated on the child has developed general tuberculosis. One patient died a short time after the operation from broncho-pneumonia, which a necropsy showed to be non-tuberculous and probably quite unconnected with the operation. It was true that the expected dangers did not occur, but what was the prospect as to the future of these cases both as to the correction of the deformity and the cure of the disease? Mr. Murray doubted very much whether this operation would effect complete and permanent cure of the deformity. The vertebræ are many of them destroyed and the interval left required to be filled by something strong enough to bear the pressure, but in tuberculous bones there was very little tendency to repair. Failing this bony formation there must be either a return of the hump or a life-long recourse to instrumental support. If the hump were filled by ligamentous tissue there would not only be a hump, but a "wobbly" hump, which would entirely incapacitate a mechanic from work, which is not the case with a rigid hump. He intended to wait to see the ultimate result in these cases before he performed the operation again, but at present he was inclined to take a somewhat unfavourable view of their future. Mr. Murray showed the spine from the patient who died from pneumonia two months after the operation, which exhibited well the great gap left to be filled up anteriorly.

The discussion was adjourned to the next meeting of the society.

OPHTHALMOLOGICAL SOCIETY.

Heredity and the Development of Myopia.—Potassium Permanganate in Ophthalmia.—Cataract Extraction.—Pseudo-Glioma due to Choroido-Retinitis Secondary to Meningitis.—Case of Albuminuric Retinitis.

AN ordinary meeting of this society was held on Nov. 11th, Mr. G. A. BERRY, Vice-president, being in the chair.

Mr. WRAY read a paper on Heredity and the Development of Myopia. He began by stating that some observers found a family history in as many as 60 per cent. of their cases of myopia. On the assumption that one-fourth of the hereditary tendencies are from each parent, and one-sixteenth from each grandparent, it was plain that heredity predisposition would appear more and more in the etiology of myopia. Mr. Wray questioned the expediency of using the term "acquired myopia" lightly, as no case could legitimately be called "acquired" unless ancestral myopia could be disproved, which he contended was impossible. He next submitted that authorities repudiated the possibility of the transmission of acquired structural peculiarities, and experimental evidence was quoted to the effect that the removal of an eye in rabbits during many successive generations failed to cause the birth of one-eyed offspring. He conceded the transmissibility of ordinary myopia, and then stated that there was no relation between the sum of the myopia of myopic parents and the amount that would appear in the offspring, and when the highest grades had been found the parental myopia was invariably confined to one parent. Since Fukala's operation had come into vogue Mr. Wray had given special care to the investigation of the antecedents of such patients, and found in a considerable number of cases that the child with very high myopia had suffered from protracted infantile marasmus, whilst the brothers and sisters who escaped had not. He further stated that out of 126 cases of myopia over 10 D he had not found one instance in which parent and child were both subject to an equal or approximately equal amount. The existence of the highest grade of myopia in one eye only made it exceedingly probable that other influences acted as powerfully as marasmus in the predisposed. Since such grave disproportions never arose in the limbs during their development, it was necessary to consider the difference in their development, and this was to be found in the way in which the vitreous was formed by the passage of mesoblastic elements into the secondary optic vesicle. Mr. Wray suggested the possibility of hypo-inclusion being the basis of hypermetropia and excessive inclusion the cause of myopia. He thought that this theory would explain the variation in the age at which myopia appears, and the phenomena of stationary and progressive hypermetropia and myopia, as well as numerous other points in the pathology of myopia

Mr. SYDNEY STEPHENSON communicated particulars of a case of Purulent Ophthalmia in an infant where the frequent use of a strong solution of potassium permanganate had given rise to a deposition of manganese dioxide upon the cornea. The mark, which was of coal-black colour, disappeared a few days after the use of the solution had been discontinued.

Surgeon-Captain HERBERT, I.M.S., communicated a paper on Cataract Extraction, in which he said that the conditions of operating were unfavourable in India, and he had found it impossible to exclude infection till he employed strong perchloride (1 in 2300) as a routine antiseptic. The lotion was used freely to the face, lids, and conjunctiva, then cocaine was instilled, the lids being kept closed to prevent the drying of the epithelium, and during the operation the surface of the eyeball was kept moist by the constant dropping of boiled saline solution. Since the adoption of this method he had performed 281 extractions; there had been no suppurations and no iritis severe enough to affect vision.—A discussion on the value of asepsis as opposed to antisepsis followed, in which Mr. BERRY, Mr. NETTLESHIP, Mr. HILL, Mr. J. GRIFFITH, Mr. LAWFORD, and Mr. CARGILL took part.

Mr. L. V. CARGILL described a case of Pseudo-glioma due to Choroido-retinitis Secondary to Meningitis in a male infant, with good family history and born at full term, who was perfectly healthy until three months old, when he suddenly developed meningitis. A fortnight later the left eye was noticed to be affected with pseudo-glioma. Two months afterwards hydrocephalus was developing and was

Digitized by Google

associated with retraction of the head. Right optic papillitis was discovered, whilst the left membrana tympani was found to be perforated, there having previously been slight purulent discharges from the left ear. The hydrocephalus increased, the left eye underwent shrinking, whilst the right eye remained unaffected except for atrophy of the optic disc. The child died about ten months after the first onset of illness. A post-mortem examination was not obtained.—Mr. TREACHER COLLINS had observed from pathological examination that these cases were more often retinitis than choroiditis. The course of the affection was from the throat by the Eustachian tube, middle ear, meninges, and optic nerve to the eye.

Dr. ARNOLD LAWSON and Dr. G. A. SUTHERLAND described a case of Albuminuric Retinitis. A girl, aged twelve years, was brought to the hospital on Oct. 29th suffering from headache and vomiting. Examination showed the presence of albumin in the urine and albuminuric retinitis in both eyes. The history of her illness consisted of intermittent attacks of headache during the last ten months. These had recently become much worse and were frequently accompanied by vomiting and great prostration. The past history was excellent. She had never had scarlet fever or any cardiac affection. She was always a ravenous eater and especially fond of meat. The family history was good except for phthisis on the mother's side. The patient was bright and intelligent and showed no lethargy. There was a diffused heaving impulse over the precordial region. The apex beat was three-quarters of an inch outside the nipple line in the fifth space. The heart's first sound at the apex was rough and accompanied by a short blowing murmur. The second sound was accentuated at the base; the sounds were clear and ringing, the second being accentuated. Arterial pulsation was visible in the large vessels of the neck. The pulse was small, regular, and of high tension, and there appeared to be some thickening of the vessel walls. The urine was acid and cloudy and its specific gravity was 1010. Albumin was present in considerable quantities. Microscopically, casts, for the most part hyaline, but also a few epithelial or fatty, were found. The fundus in each eye presented the usual changes due to albuminuric retinitis in a typical and advanced form. The case appeared to be one of primary chronic interstitial nephritis occurring at an unusually early age. The symptoms were precisely similar to those met with in adults suffering from this disease. The cause was obscure. Possibly a long course of over-feeding might have so affected the blood as to induce irritative changes in the kidney. No record of any case of albuminuric retinitis occurring at so early an age could be found. One case at fifteen years had been recorded by Mr. Benson in 1883.—Mr. NETTLESHIP called to mind two cases of albuminuric retinitis in children. One was in a boy, the details of whose case he could not recall, but who was under observation for a year; the other was in a little girl, who was said to have recently had Bright's disease. In the latter case there was great pallor of the optic nerve and old retinal changes with much impairment of vision.—Dr. BREUER said that Dr. Bull had published a series of cases, one of which was in a boy aged five years. In every case in which a post-mortem examination had been made interstitial and not glomerular nephritis had been found.—Mr. LAWFORD had recently seen a boy, aged seventeen years, with albuminuric retinitis; he also had chronic interstitial nephritis; he improved materially.—Mr. HOLMES SPICER had recently been asked to see a child at the Children's Hospital who had all the signs of acute nephritis; on examining the eyes there were a few small retinal hæmorrhages, but no large masses of exudation.

HUNTERIAN SOCIETY.

Medical Hæmorrhage.—Pruritus Vulvæ.

AN ordinary meeting of this society was held at the London Institution on Nov. 10th, the President, Dr. G. E. HERMAN, being in the chair.

Dr. F. J SMITH read a paper on Medical Hæmorrhage which is published in another part of our present issue.—Mr. COTMAN referred to the value of a large dose of sulphate of magnesia given at the commencement of a case of hæmoptysis and spoke of the value of rest as procured by opium.—Mr. GEORGE B. STEVENS said that in treatment it was often necessary to be empirical, and referred to the importance of diagnosis as a guide to treatment. He instanced a case where it was difficult to diagnose the source of the hæmorrhage which turned out to be due to a polypus nasi. He considered the old method of treatment by pilula plumbi cum opio as still the best, but he generally gave an acid mixture with ergot and digitalis.—Mr. BOWKETT said he had found benefit from ergot in large doses. In gastric hæmorrhages rest and ice were useful, whilst in most hæmorrhages turpentine by the mouth was valuable. Antimony often succeeds in pulmonary hæmorrhages when other remedies fail.—Dr. RUTTER stated that he considered the ice-bag of no use and spoke highly of the value of calcium chloride as a hæmostatic.—Dr. FORTESCUE FOX believed that the ice-bag in hæmorrhages from the stomach or intestine allayed vascular excitement. Hazeline in large doses was also useful in his experience, and he advocated venesection in cerebral hæmorrhage.—Mr. A. H. TUBBY inquired as to the reason for giving iodide of potassium and agreed with Dr. Smith's remarks on the use of ergot.—Dr. HINGSTON FOX did not use ergot for medical hæmorrhages, but used, not only iodide of potassium, but alkalies to quiet the circulation, and quoted a case of copious hæmorrhage due apparently to simple increased arterial tension without evidence of kidney lesion, and said the man was still alive.—Dr. WICKHAM still believed in the value of large doses of ergot.—Dr. ARTHUR DAVIES stated his belief in the administration of ergot in sufficiently large doses. He also referred to the value of sulphate of magnesia given frequently. He emphasised the extreme value of position in severe hæmorrhages, whether pulmonary or cerebral, and the importance of turning the patient on the affected side, as pointed out by Dr. Bowles.—Dr. SMITH replied.

Dr. HERMAN then read a paper on Pruritus Vulvæ. He first stated that though pruritus is a common complaint, yet it is important, as it causes great local suffering and indirectly, by preventing sleep, injury to health. The causes of pruritus were divided into five classes. 1. Adventitious, due to pediculi, dirt, worms, and pessaries. 2. Skin diseases—eczema, herpes, furuncle, follicular urticaria, and diabetic dermatitis, which has been shown to be due to neither saccharine urine nor sweat. 3. Irritating discharges—gonorrhœa, cancer, and senile endometritis—and also cases where no visible change is seen. 4. Venous congestion, due to heart, lung, or liver disease. 5. Nervous. In Class 1 he advised unguentum hydrargyri ammoniatum for pediculi, absolute cleanliness, and changing of material of pessary. Class 2: Eczema usually affects fat elderly women and those who are pregnant; possibly it depends on a parasitic micro-organism; in diabetes it is especially frequent. Treatment in the former consists in warm hip-baths with liquor carbonis detergens added and powdering the parts with boric acid. In the latter general treatment is required. Herpes zoster is not amenable to any kind of treatment. Follicular pruritus is best treated by squeezing out the contents of the follicles and applying a germicide lotion such as corrosive sublimate, 1 in 2000. Urticaria is very rare. Class 3: Irritating discharges should be treated by sedative and antiseptic washes to the vagina, followed by sedative powders to the vulva, such as a saturated solution of borax and dermatol powder and boric acid. When these fail to give success a strong carbolic acid lotion, 1 in 7, will in some cases completely cure or give great relief. Class 4: Pruritus is found in pregnancy and in corpulent persons with varicose veins, and those suffering from heart, lung, or liver disease. The treatment is practically the same as in Class 3. In Class 5 pruritus in aged women is sometimes a symptom of degenerative changes in the nervous system, and treatment usually fails.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Adjourned Discussion on Dysmenorrhœa.

A MEETING of this society was held on Nov. 11th Mr. MAYO ROBSON, President, being in the chair.

Mr. TENISON COLLINS (Cardiff) showed a Myomatous Uterus removed by pan-hysterectomy four days previously. The patient had so far made good progress.—

Digitized by Google

Mr. F. BOWREMAN JESSETT showed two Myomatous Uteri removed by pan-hysterectomy. In one of them an interstitial myoma had caused such absorption of uterine tissue over it as to have burst into the abdominal cavity. This specimen also illustrated a method of preserving specimens by which their colour was retained, introduced by Mr. H. G. Plimmer, pathologist to the Cancer Hospital. The fluid was made up as follows: Formalin six parts, sodium chloride one part, sodium sulphate two parts, magnesium sulphate two parts, water one hundred parts.—Mr. O'CALLAGHAN showed a Myomatous Uterus removed by the clamp method.—In the discussion on these specimens, the PRESIDENT said there were two important questions in dealing with every case of myoma: (1) Should they operate at all? and (2) if so, by what method? Many cases of hard fibroid did not require operation; but in those of rapid growth, with serious symptoms and in those that grew after the menopause removal was the only course. As to method, he was quite satisfied with a form of intra-peritoneal hysterectomy in which, after securing the vessels and suturing the peritoneum, the stump was brought up to the wound and fixed there, shut off from the peritoneal cavity, and covered by the skin.—Dr. GRANVILLE BANTOCK observed that he was not wedded to any one method; but most of his experience had been with the serre-nœud, and this had given him the best results. When there was malignant disease involving the cervix and when it was not possible to form a pedicle he removed the whole uterus. In the case of small fibroids it was a mistake to remove the uterus; many of them could be enucleated. Moreover, fibroids did not interfere with concept on, pregnancy, or labour. In a recent gynæcological text-book hysterectomy was described as an easy and safe operation. He wished to protest against such teaching; in all cases it was an operation of some difficulty, and should only be undertaken by a skilled and experienced operator.—Dr. C. H. F. ROUTH had seen many cases in which an operation had been advised by men of eminence and in which he had successfully counselled non-interference; these patients were alive now. Even when pregnancy was associated with fibroids the child would displace the tumour and delivery would be safely accomplished. He had seen many cases of fibroids, but in not one, as far as he could remember, had there been any growth after the menopause.—Dr. PURCELL said that there were cases in which it was imperative that the whole organ should be removed—viz., in cases where the myoma presented malignant characters, and for these pan-hysterectomy was the only possible operation.—Mr. BOWREMAN JESSETT, in his reply, laid stress on the disadvantages of the clamp method. On the question of myoma with pregnancy he did not at all agree with Dr. Routh; there were many cases in which it would be very negligent not to operate. Péan had shown that cases not operated upon had a very high mortality, and when abortion occurred the mortality was even higher.—Mr. COLLINS and Mr. O'CALLAGHAN also replied.

Dr. SHAW MACKENZIE showed some slides prepared from Curettings in cases of Suspected Malignant Disease. He regarded them as instances of hæmorrhagic endometritis.

In the adjourned discussion on Dysmenorrhœa Dr. MACNAUGHTON-JONES briefly reviewed the Causes of Dysmenorrhœa, and said he would confine himself to the "congestive" variety, described by Matthews Duncan as "obstructive." It was associated with flexions and under-development of the uterus, and neurasthenia. But even there there was often a difficulty, as the patient had violent dysmenorrhœa evidently attributable to the uterus, yet on examination the uterus sometimes appeared normal, while the patient's general health was good. He did not believe in simple dilatation for dysmenorrhœa; it might relieve, but it would not cure; nor did he believe in tents. He had not tried Dudley's operation, but he had had very good results from the kind of treatment mentioned by Dr. Heywood Smith at the last meeting—viz., division of the cervix with scissors; incision of the internal os with a Sims's knife; dilatation; and the introduction of a small glass stem for a few days.—Dr. HERBERT SNOW regarded dysmenorrhœa as due simply to imperfect development. A course of massage, shower-baths, and proper feeding would do a great deal; whilst he believed that if women left off the wearing of stays, or used only such as were of suitable form, much less would be heard about dysmenorrhœa.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Removal of the Scapula for Sarcoma.—Acute Diffuse Myelitis.—Chronic Intestinal Obstruction.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 5th, Dr. BRAITHWAITE, President, being in the chair.

Mr. LITTLEWOOD read the notes of a case of Removal of the Scapula for Sarcoma, in which he had operated by placing the patient in the prone position and turning inwards a large semilunar flap. The patient, a man, aged fifty-two years, who was operated upon on Aug. 16th, was shown. He had a fair amount of movement in the new joint, and could get his hand up to his mouth and to the opposite shoulder. The specimen was shown. The growth involved nearly all the bone and infiltrated some of the muscles. The whole of the bone was removed with the exception of the acromion. The growth was a fibro-sarcoma in which some of the cells were arranged in alveolar spaces.—Mr. MOYNIHAN remarked that he had lately had to excise a scapula for malignant disease in which there was only two months' history of growth; recurrence took place in a few weeks and the clavicle was removed; the disease then spread internally and the patient died in six weeks.

Dr. CAMPBELL, of Bradford, read notes of two cases of Acute Diffuse Myelitis. They both presented a fairly definite train of symptoms which, although in many respects they corresponded with those met with in the closely allied Landry's paralysis, yet in other respects were quite characteristic of acute diffuse myelitis. In both cases there was a rapidly spreading loss of power, of sensation, of both superficial and deep reflexes, and of control of the sphincters. In one the temperature was considerably raised and the course was rapid, whilst in the other (except when rigors occurred) the temperature was not materially raised and the course was somewhat protracted. After describing the cases in detail Dr. Campbell discussed the pathology of the disease and its relationship to Landry's paralysis and to acute disseminated myelitis, especially referring to the probable causal connexion of micro-organisms with all three diseases.—Dr. BRAITHWAITE, Dr. CHURTON, Dr. LEECH, Dr. GRIFFITH, Dr. BARRS, Dr. BAMPTON, Dr. EDDISON, Dr. WRIGHT, and Mr. LAWFORD KNAGGS took part in the discussion, and Dr. CAMPBELL replied.

Mr. LITTLEWOOD showed: 1. A patient on whom he had operated for Poplitial Aneurysm by removal of the aneurysmal portion of the vessel. The patient, a man aged twenty-five years, was operated on June 15th, 1897. The wound was quite healed when dressed on June 25th. He got up on June 29th, left the infirmary eighteen days after the operation, and has since been doing his usual work. He had a great deal of pain before the operation necessitating the administration of morphia, but has had no pain since. The specimen was shown. 2. A specimen of a Testicle removed from an adult. The testicle had never descended into the scrotum and the spermatic cord was completely twisted.

Mr. E. W. SELBY read a paper on a case of Chronic Intestinal Obstruction due to a Tumour of the Ileum. The patient, who was forty-five years of age, was suddenly attacked with epigastric pain and vomiting in December, 1895, and from that date until May, 1897, the symptoms recurred with increasing frequency, abdominal distension and almost complete constipation succeeding. Her weight declined from 11 st. to 7 st. On June 21st a special distension of an intestinal coil in the left iliac region was visible where peristalsis of the gut appeared to cease. She was admitted into the Doncaster Infirmary, and on July 6th an incision was made in the left iliac region and the abdominal cavity explored with the hand. The small intestine being followed upwards from its juncture with the cæcum, a firm substance could be felt a few feet up the ileum. The suspicious coil was drawn out of the wound and incised longitudinally, when a tumour was discovered attached to the mesenteric border by a short, broad pedicle. This was transfixed and ligatured, and the tumour, an ovoid mass of uniform consistence, measuring in various diameters 2 in., 1½ in., and ⅞ in., was removed. The growth was a fibroma or a fibro-myoma.—Dr. BARRS considered that in a large number of cases of intestinal obstruction abdominal percussion was useless, and in some cases absolutely misleading. He believed that visible

Digitized by Google

peristalsis always meant chronic obstruction and persistent vomiting severe disease.—Mr. LITTLEWOOD disagreed with Dr. Barrs as to the chronicity of disease where visible peristalsis was present, and spoke of two acute cases where this symptom was noticed.—Dr. EDDISON agreed with the last speaker, believing that peristalsis is frequently seen in acute cases where the amount of fat in the abdominal walls is small.

The following cases, pathological specimens, &c., were exhibited:—

Dr. GORDON SHARP: Specimens of the Mescal Button.

Dr. BARRS: (1) Ophthalmoplegia Externa, with proptosis; (2) Abdominal Aneurysm; and (3) Perforation of Intestine (enteric).

Dr. TREVELYAN: (1) A case of supposed Syphilitic Spastic Paralysis, and (2) a specimen of Multiple Tuberculous Tumour of the Brain.

Dr. HELLIER: (1) Adeno-fibroma Mammæ, with interesting secondary changes; (2) Ovarian Cyst, strangulated by twisted pedicle; and (3) Congenital Defect in Hand (patient shown).

Mr. H. S. WALKER showed a Child, nine months old, with a Malformation of the Right Auricle and Temporal Bone. The auricle was shrivelled and deformed in the usual manner but there was no meatus. The ear was dissected forwards, and there was not a mark or a depression in the temporal bone indicating any attempt at the formation of an auditory meatus. The pharyngeal end of the Eustachian tube was normal. The child was too young to notice a tuning fork. Probably as the Eustachian tube was normal there would be a more or less perfectly formed middle ear.

Mr. MOYNIHAN: (1) Endarteritis Obliterans, Subclavian Aneurysm on the Right Side; and (2) Sarcoma of the Scapula.

Mr. WARD: (1) Urinary Organs from a patient who was four times cut for stone; (2) A Case of Gastrostomy by Franks' Method; and (3) Renal Calculus removed by Lumbar Nephrectomy.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.—Midwifery.—Club-foot.

A MEETING of the above society was held on Nov. 2nd, Dr. ARNOLD EVANS, President, being in the chair.

Dr. CRAWFORD and Dr. ROBSON gave a microscopical demonstration of Living Typhoid Bacilli, and showed the changes which occur in Widal's reaction; they also exhibited Cultures of the Organism on Various Media.

Mr. FARROW showed the Heart of an Infant the victim of Congenital Heart Disease.

Dr. METCALFE read notes on 100 cases of Midwifery. Adverting to the paper of Dr. Sinclair at the Montreal meeting of the British Medical Association on "Injuries of Parturition" Dr. Metcalfe expressed the opinion that Dr. Sinclair had exaggerated the frequency of injuries arising from the more extended use of forceps by modern practitioners, and asserted that in large numbers of cases much needless suffering is avoided by the early use of forceps, and that in the hands of educated practitioners there is no corresponding tale of injury inflicted by such interference. He showed that he applied the forceps in 30 per cent. of the cases he related, that no mother had died, and only two children were born dead, and further that neither in the case of mothers nor children was there any serious injury the result of parturition.—A considerable amount of discussion followed, in which Mr. MERCER, Dr. BELL, Dr. KERR, Dr. GOYDER, Mr. HORROCKS, and Dr. RABAGLIATI took part, the general opinion being that 30 per cent. was too high a proportion for instrumental interference in midwifery cases.

Mr. HORROCKS read a paper on Club-foot, its Causation, Pathology, and Treatment. He first urged the importance of an accurate knowledge of the anatomy of the parts and showed a dissection of a child's foot the subject of Talipes Equino-varus. Mr. Horrocks limited his remarks to the condition of congenital equino-varus. Under the heading of causation Mr. Horrocks disagreed with the views that changes in the nerves or spinal cord or arrested development of the bones of the foot are in any considerable proportion of cases the prime factors in producing the deformity, but adhered to the oldest explanation—viz.: the mechanical one of the assumption of faulty or constrained positions of the limbs during intra-uterine life. Faulty positions and limitations of movement may be brought about in several ways: (1) by abdominal or pelvic growths outside the uterus; (2) by tumours of the uterine walls; (3) by limited growth of the uterus itself during pregnancy; (4) by deficient liquor amnii; (5) by some tumour of the child itself—e.g., spina bifida; and (6) by locking of the fœtal limbs. When from any of these causes the limbs assume a faulty or fixed position *in utero* the joints tend to become stiff by the formation of fibrous tissue around them and also by alteration of the cartilage, which is not in proper apposition with the corresponding articular surface. Mr. Horrocks then described in detail the anatomical changes which occur in talipes equino-varus, drawing particular attention to the displacement of the scaphoid bone, which is thrown inwards, and articulates with only the inner part of the head of the astragalus. It may articulate with the internal malleolus of the tibia. He thought that the radiograph was not of much service in estimating the degree of alteration of the bones, as there is so much cartilage present which gives only an indistinct outline. As to treatment, in mild cases the deformity can be remedied by simple manipulation and subsequent retention in good position by means of a plaster bandage or splint. The manipulations should be long-continued and systematic, care being taken to move one joint while the others are fixed. A wrench may be used to give greater power in manipulations. In the more severe cases in which the deformity cannot be reduced by hand division of the tendons and ligaments concerned or removal of portions of bone may be required before the foot can be brought into a proper position and retained there by suitable apparatus. Tenotomy is required when the foot cannot be flexed to a right angle and the inner ankle is not prominent. The tibiales anticus and posticus are first divided and then after further manipulation the tendo Achillis. If the adduction is marked the adductor pollicis and plantar fascia are to be divided, but the greatest result is given by division of the calcaneo-scaphoid ligaments. The foot is then fixed in the best possible position by plaster-of-Paris. Removal of the cuboid was practised in two cases with good results. In one case where there was very marked shortening of the inner border of the foot the metatarsal bone of the great toe was partly excised and this was followed by improvement. Mr. Horrocks insisted again that the treatment must be continuous until the child can walk in order that relapse may be prevented.—Dr. WOOD, Dr. RABAGLIATI, Mr. MIALL, and Mr. MORTON offered remarks, and Mr. HORROCKS replied.

LIVERPOOL MEDICAL INSTITUTION.

Malignancy of Villous Tumours.—Exhibition of Specimens.

A MEETING of the Pathological and Microscopical Sections was held on Nov. 11th, Mr. F. T. PAUL being in the chair.

Dr. ABRAM showed Cultures obtained from a case of Mouse Favus. He considered the parasite to be identical with that of human favus, and suggested that to multiply favus varieties alike clinically and bacteriologically was unnecessary.

Mr. PAUL read a short paper on the Relative Malignancy of Villous Tumours of the Bladder and Rectum. He quoted several cases tending to show that this growth had an amount of malignancy about equivalent to that of the recurrent fibroid and that its natural tendency was ultimately to end in carcinoma. He thought better results would be obtained clinically if the surgeon had in mind that he was dealing with a mildly malignant and not a simple papilloma.

Dr. R. BUCHANAN showed specimens and contributed a note, illustrated by lantern slides, on a Peculiar Growth in the Submucous Layer of the Walls of the Vas Deferens in the Human Adult. The exact nature of the structure was doubtful and opinions were requested from members present. The growth was about the size of a pin's head, lobulated, and microscopically showed a capsule of fine fibrous tissue and a dense collection of round cells. The structure within the capsule was tubular in character, the tubules being lined by more or less cubical cells. Within the tubules large epithelioid cells were present showing signs of degeneration.

Professor SHERRINGTON showed specimens to illustrate the Modes of Ending of Sensorial Nerves in Voluntary Muscle. He had in 1893 succeeded in demonstrating that the voluntary muscles receive a large number of sensory nerve-

Digitized by Google

fibres. In the nerve trunks supplying most of the limb-muscles about one-third of the nerve fibres are sensory. He now brought forward specimens to demonstrate the actual modes of termination of these sensory nerve fibres in muscles. He stated that, as the microscopic specimens laid before the meeting clearly showed, there are at least three different kinds of sensorial end organs in the muscles. The first of these is the *muscle spindle*, which had now been proved to be sensorial, although at first supposed to be an embryonic focus or a pathological new formation. Specimens were demonstrated which showed (1) that nerve fibres from the spinal root ganglia enter and end in these spindles; and (2) that the terminal arborisations of these nerve fibres are much larger than, and quite different from, motor end plates, and are distributed to the peculiar intrafusal muscle fibres at the equator of each muscle spindle. The second form of sensorial ending is the Golgi tendon organ. Preparations exhibiting the terminal arborisations of the nerve fibres in these end organs were exhibited confirming the original description by Golgi. The third form is the Pacinian corpuscle. These, as previously described by Professor Sherrington, are found in two situations in muscle—(1) near septa or aponeuroses; and (2) embedded in the thickness of the muscle thickness proper. Some are large, others small, and possess few lamellæ in their capsule. The nerve fibre to the Pacinian corpuscle is always a large myelinate fibre. Muscles in which they are observed are muscles of the limbs and larynx. Search for them in the eye muscles has not discovered them there. Professor Sherrington drew attention to the interesting fact that the muscle fibres inside the spindles, unlike the ordinary fibres of the muscle, do not undergo degeneration after section of the whole nerve of the muscle. Specimens were shown in which the muscle fibres inside the spindles were not shrunken in size or degenerate after the nerve of the muscle had been severed for nearly three years, no regeneration or reunion of the nerve having been allowed. The capsule of the spindle appeared a little thickened and the periaxial space a little reduced, but the intrafusal muscle fibres were undegenerate, although the muscle elsewhere was highly degenerate. Professor Sherrington found in this support for a view he had previously urged—namely, that the intrafusal muscle fibres belong to the "red" variety of muscle, which it is well known atrophies on section much more slowly than does the large "white" variety of muscle fibre. Every muscle, as Grützner and others have shown, is composed of both white and red fibres, and the latter remain comparatively unatrophied for a long time after nerve section. The communication was illustrated by micro-photograms.

The following specimens were exhibited:—

Mr. NEWBOLT: Sarcoma of the Femur.

Dr. BARENDT: Rodent Ulcer and Cirrhosis of the Liver in a Young Child.

Mr. SKELLETT SMITH: (1) Symmetrical Affection of the Finger Nails; (2) Large Hernia reaching down to the Knees; and (3) Exudation from Plastic Bronchitis.

Dr. GIVEN: Skiagrams of a Bullet in the Finger.

Dr. ABRAM: Plasmodium Malariæ, Crescent Form.

Mr. R. W. MURRAY: Spinal Column Two Months after Forcible Straightening for Pott's Caries.

Mr. THELWALL THOMAS: Trichocephalus Dispar found in the Vermiform Appendix removed for Recurring Appendicitis.

Professor BOYCE, Mr. NEWBOLT, Mr. PAUL, Dr. LESLIE ROBERTS, Dr. WARRINGTON, Dr. CAMPBELL, Dr. ABRAM, and Dr. BUCHANAN discussed some points raised.

PATHOLOGICAL SOCIETY OF MANCHESTER.

The Means by which Milk becomes Pathogenic.—Suppuration occurring in a Simple Fracture.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 10th, Mr. C. E. RICHMOND, President, being in the chair.

Professor SHERIDAN DELÉPINE read an interesting paper on the Means by which Milk becomes Pathogenic. He first referred to the influence of keeping and of temperature.[1] The influence of time he considered to be well shown by the number of specimens remaining good even at high temperature when the milk had been kept only half a day. The powerful influence of temperature on milk was still more evident, for in every category the number of good specimens was almost inversely proportional to the height of the temperature. When the clear relation existing between time of keeping *plus* temperature and the noxious properties of a certain number of samples of milk was contrasted with the ambiguous results obtained when an attempt was made to connect these noxious properties with disease of the udder it was difficult not to feel convinced that infection of the milk outside the udder and the conditions under which it is kept are the most important factors causing it to acquire at times pathogenic properties. By comparing the results of the bacteriological examination of milk which had produced outbreaks of diarrhœa and the results of his investigations, Professor Delépine found that the same bacillus was present in both cases—a bacillus resembling closely the bacillus coli communis, if not identical with it.

Mr. W. P. STOCKS related the case of a girl, aged two years and nine months, who sustained a simple greenstick fracture of the ulna which followed the usual course for two weeks and then took on acute suppurative inflammatory action leading to infection of the lower epiphysis about two weeks later and slight necrosis at the seat of fracture. No source could be found for the pyogenic cocci. Mr. Stocks referred to Kocher's experiments on the production of osteomyelitis in injured bones when the animals were fed on large quantities of putrid material, but in his case the intestinal tract appeared healthy.

Dr. JUDSON BURY showed a specimen of Aneurysm Involving the Upper Part of the Abdominal Aorta taken from a man aged thirty-nine years. Anteriorly it consisted of two rounded swellings, both above the cœliac axis; posteriorly it had ruptured behind the peritoneum, and the boundaries of the rupture consisted of eroded vertebræ (the last dorsal and first three lumbar) and retro-peritoneal tissue which was infiltrated with blood and laminated clot. The chief symptoms of the case had been rigidity of the spinal muscles in the lumbar region and severe pain and cutaneous hyperæsthesia in the back and along the distribution of the twelfth dorsal and first three lumbar roots. Pain in the back was probably the earliest symptom and began about four years before death. The patient was under observation during the last four months of his life, and in addition to the symptoms already mentioned there was a pulsating swelling in the left hypochondrium, and the pulsation could be felt behind, below, and over the last two ribs.

Mr. WESTMACOTT exhibited a specimen of Spinal Meningocele which he had removed from a child three months old. The tumour, measuring nine inches in circumference, was pedunculated and issued from the spinal column through the incomplete posterior arch of the atlas. There was no hydrocephalus before or after the operation. With Roentgen rays and a fluorescent screen the aperture in the arch of the atlas could be distinctly seen after the wound was healed.

Dr. FOTHERGILL referred to the Alleged Origin of Malignant New Growths from the Products of Conception.

The following card specimens were exhibited:—

Dr. ALCOCK: specimens of Fractured Bones in Camelus Dromedarius.

Dr. ARTHUR HELME: Uteri extirpated for (1) Fibromata; (2) Carcinoma of the Cervix; (3) Malignant Tumour of the Body; and (4) Hypertrophy and Procidentia.

Dr. KELYNACK: Carcinoma of the Gall-bladder.

Mr. HERBERT LUND: Murphy's Button *in situ* forty-eight hours after operation.

Dr. RAY: Drawings of Dissections of the Prostate Gland and the Base of the Bladder.

Mr. RICHMOND: Tumour of the Œsophagus.

Mr. PERCY STOCKS: (1) Ovarian Hernia; and (2) Hydrocele of Canal of Nuck.

Dr. E. S. YONGE: Micro preparations of Nasal and Laryngeal Specimens.

Mr. WOLSTENHOLME: Cysticercus Cellulosæ in Measly Pork.

[1] For a full account of this investigation see the Journal of Comparative Pathology, June and September, 1897.

MANCHESTER MEDICAL SOCIETY.

Amputation of the Upper Extremity.—The Appendices Epiploicæ.—Exhibition of Cases.

A MEETING of this society was held on Nov. 3rd, Dr. H. G. BROOKE, Vice-President, being in the chair.

Digitized by Google

Mr. WHITEHEAD related the particulars of two successful cases of Amputation of the entire Upper Extremity.

Mr. MONTGOMERY made a communication on the Relations of the Appendices Epiploicæ of the Sigmoid Flexure. It was shown that in the upper six or eight inches of the gut the appendices are always very much more developed on the right or mesial border of the untwisted bowel. With this fact in view the upper end of a loop drawn out in colotomy could always be distinguished from the lower, even though a twist existed. It was suggested that in colotomy for malignant disease the gut should be twisted on itself before fixation and the lower opening made the acting one. At the same time the mesenteric stitch should be passed through the abdominal wall well in the upper angle of the wound. This course would diminish the tendency to prolapse, and would give a better permanent opening with a minimum of exposed mucous surface.

Dr. GARDNER read a paper on Vomiting.

Mr. STANMORE BISHOP showed two male patients, aged respectively fifteen years and two years and ten months, upon whom Suprapubic Lithotomy with immediate Union of the Bladder and Abdominal Wall had been performed without drainage. He drew attention to the advantages of this method by which greater safety to the patient and immense decrease in the work required from the nurse are obtained.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Exhibition of Cases and Specimens.—Glandular Enlargements in the Neck.—President's Valedictory Address.—Election of Officers.

THE first meeting of this society for the winter was held on Nov. 3rd in the rooms of the Royal Scottish Society of Arts. The President, Dr. ARGYLL ROBERTSON, occupied the chair.

Professor ANNANDALE showed a male patient from whom he had removed the Larynx along with the Thyroid Gland and part of the Œsophagus. The larynx was almost stenosed by a malignant growth. He performed a preliminary tracheotomy, which required to be very low in position owing to the enlargement of the thyroid gland. He showed an ingenious arrangement for administering chloroform through the cannula a description of which appeared in THE LANCET of Nov. 6th, 1897, p. 1185. The patient seemed to be in remarkably good condition and was able himself to manipulate both the tracheotomy tube and an œsophageal tube, which had been used for feeding purposes.

Mr. A. G. MILLER showed a patient after Resection of the Ulnar Nerve. A portion of the nerve had been removed after a recurrent tumour of the arm had been excised on account of the nerve showing signs of being implicated. The gap thus left between the cut ends of the nerve was filled by splitting the end of the severed nerve longitudinally and turning one half of the nerve down and half of the lower segment of the nerve upwards. The operation was so successful that both sensation and motion had entirely returned. There was, however, a recurrence of the tumour growth.

Dr. ALLAN JAMIESON showed two cases of Lupus Vulgaris treated with Koch's new tuberculin with considerable benefit, a case of Lupus Erythematosus, and one of Dermatitis Herpetiformis.

Dr. ARGYLL ROBERTSON showed specimens under the microscope of Filaria Loa taken from the conjunctiva and other parts of the body.

Mr. CATHCART showed Fluid which had been removed from what had been diagnosed as an abscess close to the crest of the ilium, but which turned out to be a hydatid cyst.

Mr. A. G. MILLER read a paper on the Etiology and Treatment of Glandular Enlargements in the Neck. The object of this paper was to point out the importance of discovering and, if possible, removing the primary causes of glandular enlargement. He thought there were many varieties of glandular enlargement, but referred only to the simple, chronic, and the tuberculous form. He considered that it was only in the early stage that there was any difficulty in distinguishing between these conditions. He considered that simple adenitis might become tuberculous, and he spoke of this as the pre-tuberculous stage. Believing this he considered that many cases of tuberculous glands might have been prevented by a timely removal of a source of irritation. He then referred to the course of the lymphatics to various groups of glands and gave examples of some of these. Discussing causation he referred to predisposing causes such as age and constitution and exciting causes. Under the latter heading he considered the various points where organisms or their products could be absorbed. He considered that the maintenance of glandular affections was the result of the persistence of the exciting cause. He laid great stress upon the importance of shutting the door through which the infection entered. When glandular enlargements persisted after all apparent cause had disappeared or been removed the explanation was to be found in the existence of an irritating factor in the gland, which the gland could not destroy or expel, and that irritant he believed to be always tuberculous. In fact, he considered that if in these persistent glandular enlargements there was any doubt or difficulty as to their nature the probabilities were that they were tuberculous. His treatment was based upon these principles—the discovery and treatment of the primary seat of irritation—and if after that the glands continued to be enlarged he removed them.—Several of the members made remarks on the paper, and it was suggested that all cases of so-called chronic adenitis were tuberculous and showed giant-cells even if there were no areas of caseation.

The retiring PRESIDENT then delivered a valedictory oration in which he reviewed the work of the society during the time that he had occupied the chair, and made various suggestions regarding the future conduct of the society's meetings.

Dr. Batty Tuke was elected President and Dr. P. A. Young a Vice-President. Dr. Argyll Robertson, Dr. John Thomson, Dr. Michael Dewar, and Dr. Shaw McLaren were appointed to the council in place of four members whose time had expired. The treasurer, secretaries, and editor of the Transactions were reappointed.

FORFARSHIRE MEDICAL ASSOCIATION.

Hemiplegia—Simple Manœuvres for General Gynæcological Practice.—Chronic Stenosis of the Large Intestine.—Exhibition of Specimens.

A MEETING of this society was held in University College, Dundee, on Nov. 4th, Dr. ALEXANDER CAMPBELL, President, being in the chair.

Dr. STALKER communicated a case of Hemiplegia with Atrophy of the Affected Side. The case was one in which some cerebral affection of an obscure kind had existed before the hemiplegic attack, and on the apparently sound side there was evidence of descending degeneration of the cord. The theory was advanced that the nutrition of the muscles may be associated with a certain amount of intact cerebral connexion—an amount that may be supplied in an ordinary hemiplegia through supplementary aid from the sound side of the brain. When this cannot be turned to account owing to previous lesion of the side atrophy may follow.—Dr. MCVICAR suggested that an explanation of the case might be found in a diagnosis of amyotrophic lateral sclerosis.

Dr. BUIST read a paper on Some Simple Manœuvres for General Gynæcological Practice.—Dr. GREIG and Dr. KYNOCH made some comments.

Dr. MACEWAN gave notes of the case of a woman who had had symptoms of Chronic Stenosis of the Large Intestine. On the occurrence of acute obstruction an exploratory abdominal incision had shown its site to be at the hepatic flexure. In the exhausted state of the patient it was deemed advisable simply to fix some bowel at the wound with a view to an artificial anus later, but an unexpected relief to the bowels which had followed had led him to return the bowel. Some months later a recurring obstruction was treated by the excision of from four to five inches of bowel at the hepatic flexure with the use of Murphy's button. The stricture was annular and was formed by a columnar-celled epithelioma.—Dr. GREIG asked whether it was not the case that with subsequent cœliotomies there was a greater tolerance of any handling. He condemned the use of Murphy's button or any like means, and advocated end-to-end suture.—Dr. MILLER, Dr. WHYTE, and Dr. HALLEY also took part in the discussion.—Dr. MACEWAN, in reply, said that the Murphy's

Digitized by Google

button, though not without its disadvantages, might be used where rapidity of operation was required.

Dr. MCGILLIVRAY showed a patient with a Congenital Subluxation and Coloboma of the Lens.

The following pathological specimens were also exhibited:—

Dr. MACEWAN: (1) Sarcoma of the Ovary, and (2) Bronchocoeles.

Dr. FRASER: (1) Tuberculous Spleen, Liver, and Lung; (2) Atheroma of the Aorta; and (3) Carcinoma of the Œsophagus, Stomach, and Liver.

Dr. KYNOCH: Compressed Fœtus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Opening Address — Suppurating Kidney. — Genito-urinary Organs from a Case of Imperforate Anus. — Osteo-arthropathy.

A MEETING of this section was held on Nov. 5th, Dr. J. M. PURSER the President, being in the chair.

The PRESIDENT delivered his opening address.

The Secretary (Dr. MCWEENEY), in the absence of Mr. J. S. M'ARDLE exhibited an enormous Suppurating Kidney which had been removed by Mr. M'Ardle some eight days previously by nephrectomy. It was riddled with abscesses, which differed in many respects from those met with in tuberculous disease, and microscopical examination of the material which came from them did not reveal the presence of tubercle bacilli; it did, however, reveal a considerable number of organisms, plate-cultivations of which on sugar-agar showed the cylinder of substratum quite broken up by the development of gas, which is exceedingly characteristic of bacillus coli, and as the result of this gas development, and the appearance on gelatin there could be no doubt that the micro-organism contained in the pus, and probably responsible for the condition of the kidney, was bacillus coli. Bacillus coli has a tendency to invade the organs of the body post mortem, but this kidney was removed during the life of the patient and bacillus coli was the only organism found in the pus. The patient (a female) was making a good recovery.

Dr. MCWEENEY, in the absence of Mr. A. J. THORNE exhibited the Genito-urinary Organs from a case of Imperforate Anus, showing persistent cloacal arrangement, bicornate uterus, and unilateral cystic degeneration of the kidney. The fœtus (a female) was rather small and appeared to be at about the end of the eighth or commencement of the ninth month. The left kidney possessed a ureter which was at first very thin and narrow, and then becoming swollen out into a tube as wide as the small intestine was lost upon the side of the left cornu of the uterus; the right kidney was reduced to a small hydronephrotic sac and its ureter was completely obliterated. The cloaca received the orifices of the bladder, rectum, and two uterine cornua, and was continued as a narrow tube directly into the vagina, opening externally between the two labia minora. Of the proctodæum there appeared to be no trace. The previous child had been born with the left hand amputated at the carpus.

Dr. O'CARROLL showed casts and microscopical sections from a case of mixed Tuberculosis and Carcinoma of one Lung in which pulmonary osteo-arthropathy was an early and well-marked phenomenon. The patient, aged forty-nine years at death, had been a year under observation in the Whitworth Hospital. The increase in the size of the extremities was easily distinguished from that of acromegaly by the characteristic shape and by the presence of bulbar terminal phalanges.—Dr. MCWEENEY, in referring to the microscopical sections of the lung, said that he had not been able to see anything which seemed to him to give evidence of tuberculosis.

NEW WORKHOUSE INFIRMARY FOR BATH.—At the meeting of the Bath board of guardians held on Nov. 10th it was resolved that a new workhouse infirmary should be erected in accordance with plans prepared which will be sent to the Local Government Board for approval. It is estimated that the cost will be £40,000.

Reviews and Notices of Books.

A System of Medicine. By Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M.A., M.D., F.R.S., F.L.S., Regius Professor of Physic in the University of Cambridge. Vol. IV. London: Macmillan and Co. 1897. Demy 8vo, pp. 880. Thirty-one Illustrations, one Coloured Plate. Price 25*s*.

THIS volume is the fourth of the System of Medicine—or the fifth if the System of Gynæcology which appeared last year be included—and is the third that Professor Clifford Allbutt has already brought out in the present year. The rapidity with which this authoritative system is now coming out speaks highly for the energy of the editor and for the collaboration of his many writers. The leaps and bounds by which medicine is advancing and the natural desire that the reader has for the most up-to-date expression of opinion make it highly desirable that as little delay as possible should take place between the writing and the publication of contributions; it would be a lamentable thing for an author to find his article *passé* on the day that it sees the light. The life of a system of medicine can therefore be but a short one, and one of its chief functions is to mark the extent of contemporary knowledge in articles written by representative authorities on the special subjects. On having most satisfactorily achieved this consummation Professor Clifford Allbutt is to be warmly congratulated.

The present volume deals with the diseases of the liver, kidneys, and ductless glands, and enters on the consideration of the respiratory tract, the greater part of the latter section appearing here being devoted to the throat and nose. Dr. William Hunter has been entrusted with a large share of the section on Hepatic Disease and has done his work admirably. After giving in outline the salient points of its normal anatomy he proceeds to an account of the functions of the liver and their disorders; in in his systematic description of the bile and the factors influencing its excretion he prepares the ground for what he has to say later with regard to jaundice. He criticises Murchison's well-known views on lithæmia, and concludes that this condition is not due primarily to hepatic derangement, but is the result of functional disturbance or disease elsewhere. Active and passive congestion of the liver are satisfactorily dealt with, and then the much-discussed subject of jaundice is expounded in a lucid and remarkably able manner. As the outcome of an exhaustive essay on the general pathology of jaundice he concludes that all jaundice is hepatogenous and may be divided into: (1) jaundice with obstruction of a manifest character, and (2) toxæmic jaundice due to increased viscidity of the bile from intrahepatic catarrh. Obstructive jaundice is described under various heads by other authors, but Dr. Hunter deals fully with toxæmic jaundice and with the allied diseases—Weil's disease and acute yellow atrophy, &c.

Tropical Abscess is from the pen of Dr. Andrew Davidson and is a valuable source of reference, his remarks on its etiology and relation to dysentery being fully supported by statistics. In this article, which is entitled "Suppurative Hepatitis," other forms of suppuration such as pylephlebitis are included. There is a thoroughly standard article on Amœbic Abscess of the Liver by Dr. Lafleur, which is full of the results of clinical experience and original investigation. In his account of Cirrhosis Dr. Herbert Hawkins has provided a compact and practical description of the disease and has not attempted to enter into all the numerous subdivisions of cirrhosis that have been differentiated from a pathologist's standpoint; it is not so much an encyclopædic source of reference as an article that will appeal to men busy in the practice of their profession. Dr. Hale White is the

Digitized by Google

author of useful contributions on Perihepatitis and Tumours of the Liver.

The diseases of the gall-bladder and bile-ducts are appropriately described by Mr. Mayo Robson under the headings of Cholangitis and Cholecystitis, Tumours, and Gall-stones. The pathology, symptoms, and treatment are described in a masterly fashion, the section of Cholelithiasis being especially valuable and authoritative. Dr. John Thomson collects into a compact form what is known of congenital obliteration of the bile-ducts and icterus of the newly born. In these articles on the biliary apparatus the editor has been successful in obtaining the collaboration of workers who have largely added to and systematised our knowledge on the subject. This is also the case with regard to the essay on Diseases of the Pancreas, by Dr. Reginald Fitz, of Boston, whose Middleton-Goldsmith lecture in 1889 on the various forms of acute pancreatitis is so well known. He describes acute and chronic pancreatitis, pancreatic hæmorrhage, calculi, cysts, and malignant disease in a way that renders his article a most valuable source of reference.

The section on Renal Diseases begins with a clear and useful excursus on the physiology and general pathology of the kidneys by Dr. J. Rose Bradford. The accounts of dropsy and uræmia are thoughtful and philosophic, pleasantly written, and, it need hardly be added, well abreast of contemporary science. Nephroptosis, by Professor Alexander Macalister, is an exhaustive description of floating kidney and is supplied with numerous bibliographical references. The medical diseases of the kidney, under the title of "Diseases of the Kidney characterised by Albuminuria," have been very successfully handled by Dr. W. H. Dickinson. This article is freely illustrated by statistics from St. George's Hospital and is rendered more complete by an account of albuminuric retinitis from the hand of Mr. R. Brudenell Carter. Three groups of kidney disease are described; the first includes tubal, diffuse, and glomerular nephritis, the second granular kidney, and the third lardaceous kidney. Written in scholarly and charming style this article is full of practical experience and research. The "Other Diseases of the Kidney" are surgical in nature and are discussed by Mr. Henry Morris.

The next division of this volume deals with the Ductless Glands and contains several valuable articles from Dr. W. M. Ord and Dr. Hector Mackenzie. These authors, in the first place, give a summary of the present position of physiological knowledge with regard to the thyroid gland, in which the recent researches on the parathyroid glands and on the chemistry of the thyroid are clearly set forth. Dr. W. M. Ord, whose name is so closely associated with the recognition of myxœdema, gives an account of this disease and in association with his son, Dr. W. W. Ord, deals with Sporadic Cretinism. Certainly one of the best and most interesting articles in the volume is that on Graves Disease, by Dr. W. M. Ord and Dr. Hector Mackenzie; it would be hard to over-estimate the amount of research and investigation that has contributed to the production of this encyclopædic and standard article.

Dr. H. D. Rolleston's article on Diseases of the Spleen demonstrates the trend of scientific inquiry and the progress it is making in unravelling the pathology of the organs concerned in hæmatopoiesis. Indeed, his is perhaps the first systematic exposition of splenic pathology that has been attempted, and it is almost entirely owing to the work of recent years. His contribution is highly interesting and instructive, the questions raised being discussed with impartiality, but in a critical spirit. He deals first with the effects of splenectomy in man, which he shows vary in the amount of disturbance exhibited according as to whether it be a healthy spleen that is removed—e.g., on account of injury—or whether the organ be more or less impared in its function by displacement or disease. In the latter case the disturbance is slight or *nil* owing to compensatory changes having already been established; in the former the effects may be marked and severe. Dr. Rolleston gives an excellent account of the spleen in bacterial infection and toxæmia, and shows that as regards the first-named it probably has no special protective power which "cannot be vicariously assumed by other organs such as the lymphatic glands." In discussing the part played by the spleen in anæmia he expresses the opinion that splenic anæmia is rather the result of a toxæmic condition than of splenic inadequacy. He shows that the spleen has no share in chlorosis, but that it may take part in the hæmolysis of pernicious anæmia. The general disquisition is followed by a description of the special pathology of the organ.

Dr. Rolleston also writes upon Addison's Disease, the pathology of which he discusses with marked ability and knowledge. He does full justice to the views advanced by others to explain the phenomena of this affection, and gradually leads up to the conclusion that the hypothesis of suprarenal inadequacy best accords with the facts. Thus the original surmise of Addison that the symptoms are to be accounted for by derangement of the suprarenal function finds confirmation in the latest teachings of science which attribute them to the effects of deficient production of the internal secretion of these glands, either by inducing a toxic state of the blood or by the general atony and apathy due to the absence of the stimulating influence of this secretion. The symptomatology, diagnosis, and treatment of Addison's disease are well described, considerable attention being paid under the last head to the recorded results of treatment by suprarenal extract.

Lymphadenoma or Hodgkin's Disease is carefully described by Dr. G. R. Murray who gives numerous references to the results and opinions of other writers on this difficult and rather confused subject.

It must be regretted that the only article which the editor has allowed himself to write is a very short one, viz., that on Scrofula; the surgical aspect of tuberculous adenitis of the neck is treated by his former colleague Mr. T. Pridgin Teale.

Sir Dyce Duckworth gives a dignified account of Obesity, in which he enters fully into the physiological and pathological aspects of the question. Heredity is an important factor in its causation so that there is a special diathetic condition at work, as definite in its course as a gouty or strumous disposition; the various forms of treatment are dealt with in well considered terms.

The number of the respiratory diseases included in this volume is comparatively small, being limited to those of the nose, pharynx and larynx. But there are three introductory articles, the first on the General Pathology of Respiratory Diseases by Dr. Ransome, F.R.S., is well illustrated by charts showing the movements of the chest wall under various conditions. The same author describes the treatment of asphyxia. The physical signs of pulmonary disease and the problems of the conduction of sound are elucidated by Dr. Hector Mackenzie.

Sir Felix Semon has arranged the valuable section on the Diseases of the Nose, Pharynx, and Larynx, which really forms a little system in itself. The other contributors are Dr. de Havilland Hall, who brings his experience as a general physician to bear on the throat affections of the specific fevers and has in addition given useful summaries of a number of diseases of the nose and throat, and Dr. Greville MacDonald, who writes on new growths, bone affections, and diseases of the accessory cavities of the nose. Sir Felix Semon and Dr. Watson Williams have together borne the brunt of the labour in this department, and we are indebted to them for authoritative articles on nasal neuroses, adenoid vegetations, syphilis, stenosis, and new growths, &c., of the

Digitized by Google

larynx and most of the important sections on the pharynx, including the diseases of the tonsil.

This brings to a conclusion the fourth volume of Professor Clifford Allbutt's System of Medicine and we have again to congratulate him on the continued success that has attended his arduous labours as editor.

Dictionary of National Biography. Edited by SIDNEY LEE. Vol. L.: Ruszen—Scobell. Pp. 456. Vol. LI.: Scoffin—Sheares. Pp. 463 London: Smith, Elder, and Co. 1897. Price 15*s.* each.

SHAKESPEARE is, no doubt, the most important figure in these two volumes. The biography of him is by Mr. Sidney Lee, the editor, and occupies fifty pages. Next in order of literary eminence comes Sir Walter Scott, the article on whom is by Mr. Leslie Stephen, and extends to twenty-six pages.

The biographies of medical men in the two volumes are fifty in number, not including, however, in this total the first Marquis of Hertford (1588–1660), who graduated B.A. at Oxford University in 1607, was created M.A. in 1636, and D.Med. in 1645. He was Chancellor of the University from 1643 to 1647, and again in 1660. William Rutty was born in London in 1687, graduated as M.D. at Cambridge University in 1719, was elected a Fellow of the College of Physicians of London in 1720, and delivered the Gulstonian Lectures in 1722. He held three of the lectureships at the Barber Surgeons' Hall—namely, the Osteology Lectureship in 1721, the Viscera Lectureship in 1724, and the Muscular Lectureship in 1728. He became second secretary of the Royal Society in 1727, and died in 1730. William Saunders was born in Banff in 1743 and graduated as M.D. at Edinburgh University in 1765, after which he removed to London. He was admitted a Licentiate of the College of Physicians of London in 1769, was elected a Fellow in 1790, was a Censor on four occasions, and delivered the Gulstonian Lectures in 1792. "He was probably the first English physician to observe that in some forms of cirrhosis, then called scirrhosity, the liver became enlarged and afterwards contracted." He delivered the Harveian Oration in 1796, in which he praises the recent discovery of the cause of Devonshire colic (a form of lead poisoning) by Sir George Baker. From 1770 to 1802 he was a physician to Guy's Hospital. In 1793 he was elected a Fellow of the Royal Society, and in 1807 was appointed physician to the Prince Regent. In 1805 he was chairman of a meeting which led to the formation of the existing Royal Medical and Chirurgical Society, and he was its first President. He retired from practice in 1814 and died at Enfield in 1817. Isaac Schomberg was born in Germany in 1714, his father being a medical man who removed to London about 1720. He commenced to practise medicine at an early age, not having any English qualification, and was consequently in 1746–47 summoned before the President and Censors of the College of Physicians to present himself for examination as a Licentiate, but declined the invitation. In 1747 he was entered at Trinity College, Cambridge, and in 1749 he obtained by Royal mandate the degree of M.D. from the University. In 1747 he was by order of the College of Physicians of London interdicted from practice and a protracted and expensive litigation ensued. He was, however, admitted as a Licentiate in 1765, was dated a Fellow in 1771, and was Censor in 1773 and 1778. He died in 1780. Edward James Seymour was born in 1796, graduated as M.D. at Cambridge University in 1826, and was admitted a Fellow of the College of Physicians of London in 1827. At the College he subsequently held the posts of Gulstonian Lecturer in 1829, Censor in 1830, Croonian Lecturer in 1831, and Consiliarius in 1836. From 1831 to 1839 he was a metropolitan commissioner in lunacy. He published several works and died in 1866. Charles Scarburgh was born in London in 1616, graduated as M.D. at Oxford University in 1646 and at Cambridge in 1660, was elected a Fellow of the College of Physicians of London in 1650, and was Censor three times. He was a friend of Harvey, who bequeathed to him some articles, and whom he succeeded as Lumleian Lecturer in 1656. He was physician to Charles II., James II., and Queen Mary. He was knighted in 1669 and was one of the original members of the Royal Society. He died in February, 1693–4. John Rutherford was born in Selkirkshire in 1695, studied medicine in London, Leyden, and Paris, and graduated as M.D. at Rheims in 1719. In 1721 he settled in Edinburgh, and in 1726 was appointed to the chair of Practice of Medicine in the University, where he delivered lectures in Latin until 1765, when he resigned. In 1748 he was granted permission to give a course of clinical lectures in the Royal Infirmary, and in this way was laid the foundation of the clinical teaching for which Edinburgh afterwards became so celebrated. His eldest daughter was the mother of Sir Walter Scott. He died in 1779. His son, Daniel Rutherford, born in 1749, took the degree of M.D. at Edinburgh University in 1772, his inaugural dissertation being, "De aere fixo dicto aut mephitico." This tract owed its importance to the distinction, clearly established in it, between carbonic acid gas and nitrogen. Joseph Priestley had published a memoir on the same subject six months previously, but his exposition is less methodical and precise. Rutherford became a Fellow of the Royal College of Physicians of Edinburgh in 1777, and was President of the College from 1796 to 1798. He was appointed Professor of Botany in the university in 1786, and died in 1819. Nathanael St. André (1680–1776), a native of Switzerland, came to England and was placed with a surgeon of eminence, who made him an anatomist. He practised as a surgeon, and his knowledge of German induced George I. to appoint him "Anatomist to the Royal Household," but it is probable that he was an unqualified practitioner. In 1726 he became involved in the imposture of Mary Tofts, of Godalming, who professed to be delivered of rabbits. St. André avowed his belief in the woman's statements, but the fraud was exposed by Dr. Douglas and Sir Richard Manningham, M.D.

William Rutherford Sanders was born in 1828, received his early education in Edinburgh, subsequently studied medicine there and graduated M.D. at the university in 1849, obtaining a gold medal for his thesis on the Anatomy of the Spleen. After two years spent in Paris and Heidelberg he returned to Edinburgh, and while temporarily occupying the position of pathologist in the Royal Infirmary in 1852 he studied certain degenerations (afterwards called amyloid), particularly as affecting the liver and spleen. In 1853 he was appointed conservator of the Museum of the Royal College of Surgeons of Edinburgh. From 1855 onwards he lectured in the extra-academical school on physiology and histology, and in 1861 he was appointed physician to the Royal Infirmary. His first literary contributions to clinical medicine were papers on Pseudo-Paralysis Agitans and on Facial Hemiplegia. He afterwards took up the subject of aphasia, and furnished articles on Nervous Disease to Reynolds's System of Medicine. In 1869 he was appointed to the chair of Pathology in the University. In 1880 he had an attack of right hemiplegia, together with aphasia, amounting to almost absolute inability to make use of either speech or writing. He died in 1881. Humphry Sandwith was born in Yorkshire in 1822, studied medicine in London, and in 1846 passed the examinations of London University and of the Royal College of Surgeons of England. In 1849 he went to the East, first to Constantinople and then to Nineveh with Sir Austen Henry Layard. He held an appointment as surgeon in the Turkish army during the Russian war, serving on the Danube in 1854 and in Kars in 1855. When Kars surrendered to the Russians Sandwith

Digitized by Google

was set free by General Mouravieff in consideration of his humane treatment of the Russian prisoners. When Servia declared war against Turkey in 1876 he went to Belgrade to join the Servians, also collecting money for them in England and writing in the English newspapers against intervention in favour of Turkey. Sandwith was the author of several books relating chiefly to Turkish affairs. He died in Paris in 1881. William Scovell Savory was born in London in 1826, graduated as M.B. at London University in 1848, became a Fellow of the Royal College of Surgeons of England in 1852, and in 1859 was appointed lecturer on general anatomy and physiology at St. Bartholomew's Hospital. In 1861 he became assistant surgeon to the hospital and was surgeon from 1867 to 1891. He was appointed lecturer on surgery in 1869 and held the office for twenty years. In 1885 he was elected President of the Royal College of Surgeons, and held the office for four years, the longest tenure in the history of the College. He was Hunterian Professor of Comparative Anatomy and Physiology from 1859 to 1861, Bradshaw Lecturer in 1884, and Hunterian Orator in 1887. In 1879 he delivered at Cork an address which was a declaration against the antiseptic method of Lister and was "the last public expression by a prominent surgeon of opposition to the now universal method of modern surgery." He was created a baronet in 1890 and died in 1895. John Scouler was born in Glasgow in 1804, studied medicine at the university there, and entered the service of the Hudson's Bay Company as surgeon and naturalist. Returning to Glasgow he graduated as M.D. in 1827, and in 1829 was appointed Professor of Geology and Natural History and Mineralogy in the Andersonian University (now part of the Glasgow and West of Scotland Technical College). He was the author of many papers on natural history subjects, and, in conjunction with two medical colleagues, established the *Glasgow Medical Journal*. He died in 1871. Charles Scudamore was born in Kent in 1779, studied medicine in London and Edinburgh graduated as M.D. at Glasgow University in 1814, and then settled in London. He went to Ireland in 1829 in attendance on the Duke of Northumberland, then appointed lord-lieutenant, who knighted him the same year. He was the author of several works on mineral waters, rheumatism, &c. He died in 1849. Edward Cator Seaton was born at Rochester in 1815, graduated as M.D. at Edinburgh University in 1837, and settled in London in 1841. He was connected with the Epidemiological Society from its foundation in 1850. A report on small-pox and vaccination, drawn up by him on behalf of the society, was presented to Parliament and led to an inquiry which resulted in the passing of the Compulsory Vaccination Act in 1853. In 1858 he was appointed an inspector under the General Board of Health, from 1871 he acted as assistant medical officer to the Local Government Board, and in 1876 succeeded Sir John Simon as medical officer. He was the author of numerous memoirs and reports on small-pox and vaccination. He died in 1880. William Sharp was born near Leeds in 1805 and was admitted a Member of the Royal College of Surgeons of England in 1827. He was elected a surgeon to the Bradford Infirmary in 1829 and became its senior surgeon in 1837. He left Bradford in 1843, proceeding first to Hull and then to Rugby, where he was the means of establishing science teaching as part of the curriculum of Rugby School. Dr. Sharp died in Wales in 1896. In 1856 the degree of M.D. was conferred on him by the Archbishop of Canterbury, a method of graduation which formed the subject of an article in THE LANCET on the occasion of his death.[1] William Sharpey was born at Arbroath, in Forfarshire, in 1802, studied medicine in Edinburgh and Paris, and graduated as M.D. at Edinburgh University in 1823. He then spent some years on the continent, and returning to Edinburgh commenced to lecture on anatomy in the Extra-mural School in 1831–32. In 1836 he was appointed to the chair of anatomy and physiology at University College, London. His biographer, Mr. D'Arcy Power, says that "his lectures proved of the greatest importance; they were models both in matter and form. They were continued for the long period of thirty-eight years and were always largely attended." Sharpey died in 1880. He was one of the secretaries of the Royal Society from 1853 to about 1871.

[1] THE LANCET, April 25th, 1896, p. 1146.

Clinical Diagnosis: the Bacteriological, Chemical, and Microscopical Evidence of Disease. By Dr. RUDOLF V. JAKSCH. Translated from the Fourth German Edition and Enlarged by JAMES CAGNEY, M.A., M.D. Third Edition. London: C. Griffin and Co. 1897. Price 28*s*.

THERE is no need to say anything here in commendation of Dr. von Jaksch's manual. On its first appearance it was warmly received on all sides for its thoroughness, accuracy, and practical teaching, and the success which it has attained, not only in Germany, but in the various countries where translations of it have appeared, proves that the reception it had was well warranted. Each successive edition has been carefully amended by its author, and this English edition has received many valuable additions by the translator, Dr. Cagney. The chapters on the Blood and on the Urine are perhaps the best in the book, which is a mine of information upon everything connected with the work of the clinical laboratory. To those engaged in original research in the wider range of subjects which it comprises such a work as this is well-nigh indispensable, supplemented as it is by a most compendious bibliography. But it is also of great value to the teacher and to the advanced student, and is an evidence of the remarkable extent to which the collateral sciences come to the aid of medicine. We have already on previous occasions dwelt at length upon the salient features of the work, and may content ourselves with welcoming the appearance of this third English edition, which in typography and illustration is most excellent.

Mitteilungen aus den Hamburgischen Staatskrankenanstalten. Band I., Hefte 2 und 3. (*Reports of the State Hospitals of Hamburg*, Vol. I., Parts 2 and 3.) Hamburg. 1897.

THESE publications form the second and third divisions of the first volume of the Hamburg Medical Reports. In the second division are eleven communications on various subjects. The first is by Dr. Gustav Zuschlag, on the Use of the Continuous Bath in the new hospital at Hamburg-Eppendorf. The author gives details of several conditions in which he has found this treatment useful, and mentions more particularly multiple tuberculous joint affections, and septic wounds. Amongst the other communications are some papers on surgical operations, which will be read with interest, notably the one on Surgical Treatment of the Cerebellum, by Dr. Janz. In the third division are no less than seventeen communications, many of them of the greatest interest. Professor Lenhartz contributes an article on the diagnosis of small-pox from chicken-pox, which is accompanied by well-executed illustrations; so also is the paper by Dr. Th. Lochte on a Case of General Neurosis of the Vessels with Peripheral Gangrene (so-called Raynaud's disease). One of the best articles is that by Dr. Karl Küstermann on Investigations on Beri-beri. A post-mortem examination on a case is described in which rather unusual changes were found, more particularly degeneration of the vagi about the level of the carotid vessels, which probably had a causal relationship with the severe cardiac attacks from which the patient suffered. The fibres of the external popliteal nerve were also found to be degenerated. Certain changes hitherto undescribed were

Digitized by Google

found in the muscles. Another article worthy of note is by Dr. M. Simmonds on Changes of Form Observed in the Trachea. Dr. Erich Wille writes a paper on the Morbid Anatomy of the Pancreas in Diabetes, illustrated by drawings of microscopic specimens. Another important communication is by Dr. H. Wilbrand and Dr. A. Staelin on Pathological Changes in the Eye Occurring in the Early Stages of Syphilis.

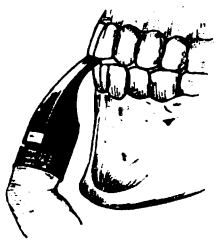
JOURNALS AND REVIEWS.

The Phonographic Record.—Two Cases of Malignant Abdominal Tumour, by Dr. H. Couper Patrick, is the title of the opening paper in the *Phonographic Record* for November. Mr. Herbert Caiger, F.R.C.S. Eng., has an interesting note on an Obscure Case. A male Kaffir child, aged seven years, was found lying unconscious. There were clonic convulsive movements of the face, especially of the right side of the mouth. The right arm was very soon afterwards affected with similar movements, which a few minutes later spread to the right leg. The left arm and leg were flaccid and motionless. The convulsions subsided after lasting several minutes. The pupils were equal and of medium size. After a short interval the convulsive movements recommenced. The march of the spasms was very definite. Horizontal movements of both eyes occurred, then up and down movements of both eyebrows. Movements of the nostrils and mouth occurred. The clonic spasms were much more marked on the right side, the arm and shoulder, and finally the leg became affected, while the left limbs remained unaffected. After two or three of the spasms had been observed it was found that compression of the left carotid artery checked the spasms as long as it was efficiently kept up. The diagnosis first made was intracranial hæmorrhage. The case was first seen about 6.30 P.M., and the next morning the patient was found to be perfectly conscious, with no apparent paralysis. An examination of the heart revealed a "to-and-fro" movement, and the diagnosis was changed to mitral stenosis with embolism of one of the smaller cerebral arteries. The interesting points in the case are: (1) that embolism may produce such convulsions, and (2) that compression of the carotid artery checked these convulsions. Dr. A. Hill Joseph writes some interesting notes of cases illustrating the influence of one disease upon another.

The Westminster Review.—Dr. H. Baptist Crofts has an interesting paper entitled "Victorian Medicine," in which he pleads for the further cultivation of a school of medicine considered as pure science, and argues that most of the real advances made in medicine during the Victorian era have arisen from the study of biology. In the "Independent Section" Mr. W. T. Freeman, F.R.C.S. Eng., argues against the Darwinian theory of evolution as he considers that there are "countless original forms which always have been and always will be." We do not say that we agree with him, but his paper is worth reading.

Pearson's Magazine.—This popular monthly has a story in it which we can only characterise as quite unfit to appear in a lay journal while it is written by one ignorant of what he is writing about. It is called "The Microbe of Death," and the teller is a medical man called by the author Sutherland Huntingdon. His moral point of view may be gathered from the following: "What is remorse? Fear of detection. I can never be found out. Why, then, should I feel remorse?" Dr. Huntingdon's remarks are a gross plagiarism from those of George De Barnwell, who, it will be remembered, said on the night before his execution: "It may be an error of judgment, but it is no crime. Were it crime I should feel Remorse. Where there is no remorse Crime cannot exist. I am not sorry; therefore I am innocent." Dr. Huntingdon's views on the subject of anthrax poisoning are peculiar. His victim died from inoculating his finger by a scratch from a bone during a post mortem examination on a man who had been inoculated with anthrax just before his death. In such a case a pustule would almost certainly have appeared at the site of the puncture by the bone, yet it is specially mentioned that there were no local symptoms. Stories of this sort are not pleasant reading for the public and give a grossly unfair description of the medical profession while they disseminate extraordinary pathological errors.

The Strand Magazine has a remarkable story of human endurance entitled the Greatest Athletic Feat on Earth (?). The story is told with the air of probability that the old stories in *Blackwood* were wont to wear, and with strict attention to detail and statistical adnexa, so that the writer convinces us against our wish of the truth of the narrative. Dr. Conan Doyle's serial story, The Tragedy of the *Korosko*, has reached a very exciting point.



The Contemporary Review.—Sir Edmund Verney contributes a popularly written but sound article on the Bacteriology of Milk, a very important subject, not only from the point of view which regards milk as a carrier of infection, but also on account of the influence which certain bacteria have upon the flavour and keeping qualities of butter and cheese.

Knowledge.—The literary supplement of the November issue of this magazine is prefaced by a signed article by Mr. R. Lydekker dealing with the study and use of scientific literature. The keynote of the article is found in the opening paragraph, in which the author says: "The great difficulty that besets both the professional and the amateur student of natural science at the present day is to find out what has already been written on the subject he may have in hand." This applies as much to medical literature as it does to the literature of other branches of science. In Neale's Digest we have an indispensable aid, but for reasons best known to themselves members of the profession do not consult the work regularly.

New Inventions.

A MOUTH-OPENER.

MESSRS. WEISS AND SON, of 287, Oxford-street, W., have just brought out a little appliance which is intended for the use of anæsthetists. It has been designed by Dr. Frederic Hewitt with the object of affording a ready and rapid means of opening the mouth of the semi-anæsthetised or anæsthetised patient. Owing to the frequency with which the upper teeth overlap the lower it is often impossible to relieve obstructed breathing by the customary plan of pushing the lower jaw forwards, and it therefore becomes necessary to open the mouth. If the teeth are tightly clenched, and more especially if there are no vacant spaces between them, it is by no means an easy matter to do this. The difficulty reaches its acme in the case of powerfully built men whose upper teeth considerably overlap the lower. The little appliance here figured is made of brass and is in reality a curved finger shield, more or less wedge-shaped, which can be introduced, as shown, beneath the overlapping upper teeth. When the thin end of the wedge has gained admission the mouth-opener is pushed onwards till the teeth are separated by the large end, at which two slots are cut, one through the upper and the other through the lower wall. When once the teeth have fixed themselves in these slots the finger may be taken out of the instrument and the mouth will remain open without further assistance.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 20, 1897.

THE General Medical Council will on Tuesday next, Nov. 23rd, assemble for its Sixty-third Session. The President's health will not, unfortunately, admit of his attendance. Nevertheless, he takes great interest in the business of the Council and exercises a keen supervision over it, but he will, it is understood, ask some other member of the Council—probably Sir WILLIAM TURNER—to act for him as President. It is long since the General Medical Council met without Sir RICHARD QUAIN'S presence, and his absence from their midst will be a regrettable event to all the members. Three other changes in the constitution of the Council will be noticeable. Sir JOHN BANKS, the Representative of the Royal University of Ireland, whose genial nature and courtly manners have made him a personality in the Council since 1883, has resigned, and he will be replaced by Sir CHRISTOPHER JOHN NIXON. Dr. WILLIAM MOORE, the Crown Representative for Ireland, has also resigned and his successor has not yet been appointed. Mr. VICTOR HORSLEY will appear for the first time at the table of the Council in the honourable position of a Direct Representative for England and Wales, where he may be expected to increase the liveliness of the Council's discussions while inviting it to take a more extended view of its own functions and powers.

It is not easy in the absence of a set programme to forecast the nature of the subjects which will mainly occupy the attention of the Council. But it is not altogether impossible to do so, and some of them are to be of exceptional importance to the profession. A reference to the minutes of the last meeting will suggest that preliminary education will be one of these. We gather that the Education Committee is entrusted with the duty of reporting on the best means by which the standard of preliminary education in the various educational bodies can be raised. The Council is unanimous in its determination to raise the standard. The only differences of opinion that can arise between members will have reference to the extent to which this change should be carried and to the amount of time requisite in which to give due notice to educational bodies at home and in the Colonies and India. The step is most reasonable. The standard of general education is being raised, and it is obvious that a sound scientific education in medicine needs for its basis a more sound general education than was thought necessary a generation since. A second feature of the November meeting will be the appearance in a practically complete form of the new edition of the British Pharmacopœia. It is an open secret that the President, as chairman of the Pharmacopœia Committee, has watched the preparation of this work with parental interest. We can only express the hope that it will prove to be constructed on such views as will meet the wants of the practitioners of an empire under whose skies may be found every variety of climate and disease and whose soil possesses and nourishes every form of drug, whether mineral or organic. The question of midwives may be expected to come on the *tapis*. The Bill before the Parliament of last session was sent down by the Lords of the Privy Council for the consideration of the General Medical Council and, as our readers will remember, it was referred to a Committee. A report from this Committee may be expected. It will doubtless be of such a nature as will reflect the gravity of the subject, and it may be expected to recognise that a lying-in woman in poverty is entitled to the peculiar consideration of the State. The delay in disposing of this subject is not creditable. Its periodical reappearance in the Council is a source of enormous expense to the Council, and the Government cannot much longer have any doubt as to the general principles on which such legislation as is demanded should be based. The great object of the Council should be to secure that in some practical way or other the supervision of the profession is ensured to every lying-in woman who needs it. Yet another subject of almost greater interest and of quite equal difficulty to be brought before the Council is that of medical aid associations in their ethical rather than their medical aspects. It will be remembered that various memorials from Norwich, Yarmouth, and other places were referred by the Council to the consideration of a Committee. The report of this Committee may be expected at the approaching meeting, when it is most sincerely to be hoped that the profession will receive some luminous suggestions for guiding the action of individual practitioners in accepting medical office in such institutions, especially under conditions which do not allow of efficient medical service or which violate the decent rules which regulate medical practice.

Various subjects of moment were referred to the Executive Committee for further consideration. One of these was the question whether the Council's position towards unqualified assistants might not with advantage be made more clear and stringent. The coming session will be curiously unlike its predecessors for several years if it does not supply instances of practitioners being compromised or put into a very unfortunate position by the employment of unqualified assistants. Many such practitioners plead ignorance of, or inability to understand, the Council's attitude. But apart from the question of clearness it is undeniable that both in the profession and in the Council there is a growing feeling that the time has come for curtailing greatly the functions of the unqualified assistant. The Executive Committee will also have before it—and not for the first time—the subject of the disciplinary powers of the various medical authorities over their ill-behaving diplomates or graduates. It is gratifying to see in most of these authorities a desire to possess disciplinary powers corresponding to their powers of granting a licence to practise medicine, whether in the form of a degree or a diploma. But in some quarters whence better things might be expected there is a strange reluctance to use such powers where they exist or to acquire them where they are not possessed. This is not as it should be.

Digitized by Google

On the contrary, we feel very strongly that distinctions given by universities and corporations should be capable of withdrawal for sufficient reasons by the bodies which granted them and that all self-respecting educational authorities should strive to be placed in this position. But we have said enough to show that the Council has ample material for several days' business.

ON Friday, Nov. 12th, Mr. TUBBY and Mr. ROBERT JONES read two papers at the Clinical Society of London on a method of treatment that has already been described and illustrated in the lay press as a "modern miracle." Several months ago we first heard of the re-introduction under an altered form of an old and discarded treatment of Pott's disease of the spine, which aimed at nothing less than the immediate straightening of angularly curved spines by the application of a combination of longitudinal extension and vertical pressure over the gibbosity. About sixty years ago an English surgeon—Mr. HARE—published a small work on the treatment of this disease in which he advocated the forcible straightening out of bent spines, and in which is figured an apparatus differing but little from the one used for the forcible extension practised in Liverpool, but he does not seem to have supplemented this by the application of vertical pressure to directly open out the curve. He, however, figures a case before and after treatment in which he obtained a result fully equal to any claimed by the more recent surgeons in their successful cases. It would be wholly wrong to use the abandonment of Mr. HARE'S treatment as an argument against the use of M. CALOT'S treatment, for the conditions are not the same. M. CALOT, who was present and spoke at the meeting, uses an anæsthetic, which not only renders the process of extension painless, but nullifies the resistance of the muscles to the extension. Then the method of extension by six strong assistants is obviously more powerful than was Mr. HARE'S, and the addition of direct vertical pressure over the convexity of the curve adds considerably to the efficiency of the straightening process. And, again, the subsequent fixation and support of the spine in the corrected position in a plaster-of-Paris casing is an entirely new element in the treatment. We may therefore say that while the motive of the treatment is not new, yet the mode of carrying it out is so altered and improved that it may fairly claim to be a "new" treatment.

It was evidently in accord with the fitness of things that this new treatment should come up for discussion at the Clinical Society of London, which was founded solely for the purpose of investigating the clinical features of disease and especially the effects of treatment. At the discussion the papers and also the photographs displayed by a lantern demonstration of patients before and during treatment clearly showed (1) that angular curves of the spine can very generally be straightened out at once or in two or three sittings by the exhibition of an amount of force well within the limits of safety; (2) that this treatment is not attended with grave immediate danger if carried out with due care; and (3) that curves of long duration and great extent may yield to this treatment. But, strange to say, neither Mr. TUBBY nor Mr. JONES showed the result of this treatment in even a single instance, and the demonstration was of value and interest solely as indicating the method adopted and the extent to which curves of the spine will yield to force. We feel sure that these gentlemen appreciated and regretted this defect in their demonstration as much as the other members of the society did and that they will take steps to make it good. Sufficient time has not yet elapsed to allow of their showing the final results obtained. But this being so we can only regard the demonstration as altogether premature and not fitted to initiate a useful discussion. *A priori* arguments may be ingenious, but they are neither scientific nor convincing. Facts are what we want, and the Clinical Society exists for the collection and sifting of facts, and until the surgeons who have practised this treatment for spinal caries have completed their cases and can not only tell us but *show us* their final results, to discuss the treatment is a barren pursuit. Who cannot see the initial charm of the treatment? But who also cannot see the possible—nay, probable—evils that beset it? But neither the charm nor the fear would weigh against proved results, and until we have these results there is really nothing to discuss.

We feel it our duty to enter this protest. Incomplete publication of methods of treatment is always mischievous, and never so mischievous as when the publication takes place in the lay press. We can all remember as a terrible warning the premature publication of KOCH'S "cure" for tubercle, the cry of *à Berlin* and the widespread disappointment which followed and which has left behind it a serious distrust of medical innovation. Already some of the same photographs as were shown by M. CALOT at the Clinical Society have found their way into a lay journal and the public have been excited by a partial description of a "miracle." This is not creditable to the profession, and the Clinical Society will do well to call to mind the rules which its founders laid down for the investigation of disease and not to accept without demur a merely partial account of a procedure in surgical treatment which is either a great boon or a great mistake.

SEVERAL suggestions have recently reached us as to the need for an amendment of the Infectious Disease (Notification) Act, 1889. On Nov. 6th we published a letter from Dr. YOUNG, the Medical Officer of Health for Crewe, with reference to the action of Crewe Town Council in memorialising the Local Government Board and pointing out that a change in existing law is necessary. The subject is again referred to in a letter in our issue of to-day from Mr. GARSTANG, the Medical Officer of Health for the Bucklow Rural District, explaining the similar action which has been taken by his sanitary authority. Mr. GARSTANG urges the importance of fresh legislation and also makes certain suggestions as to points that are somewhat in dispute. We may state at once that we are entirely in agreement with those who press for amending legislation, and that we believe the time has come for making the Act compulsory throughout England and Wales. The total population of England and Wales was estimated in March, 1896, to be 29,002,525, and notification of infectious

Digitized by Google

disease is already in force in districts having an aggregate population of 26,985 852, as well as in 40 port sanitary districts. Surely the time has come when the country as a whole should no longer be deprived of the full advantages of the system of notification of infectious diseases merely because two millions out of thirty millions of people do not want to know the extent to which such disease exists in their districts. We are further in agreement with those who urge that the time has come for abolishing dual notification of the same case of disease—that it is to say, by householder and medical practitioner. As a matter of fact the requirement is a dead letter. But a householder who does not call in a medical practitioner until late in the disease should not be allowed to escape the penalty for having failed to notify as soon as he became aware of the nature of the disease merely because he has called in a medical notifier at a later stage. Such points as this will have to be guarded against.

Notification is now made compulsory on "becoming aware" that the patient is suffering from a notifiable disease, and it is suggested that the proof of not being "aware" should rest on the person who fails to notify. This is a provision that would be much resented in its application to the medical profession as a whole, however convenient it might be to some medical officers of health. It rests on the assumption that medical practitioners will wilfully conceal the existence of infectious disease in their patients, and whatever disinclination there may have been as to revealing such matters some years ago we believe it no longer prevails to any conspicuous extent, so that it is quite unnecessary to place medical practitioners in a legal position which would reflect in an unbecoming—nay, a degrading—manner upon their honour as well as their intelligence. But where concealment can be proved we admit that the penalty should be heavy—indeed, a fine can hardly be too heavy where such concealment has been attempted by the owners of laundries, bakeries, and dairies, the persons to whom Mr. GARSTANG has referred in his suggestions for legal amendment, and who are obviously liable to temptation in a special degree, and in the same degree are potent for mischief. Another suggestion which has been made is that when one certificate has been given in a case no further certificate should be paid for the same case. We see no objection to this provided the second medical practitioner who may be called in sees the patient together with, or in association with, the medical man who has already notified the disease, and provided the diagnosis of the second comer is the same as that of the first practitioner. But if a separate medical practitioner is called in independently then he should notify quite apart from there having been a previous medical visit, of which he may know little or nothing. Indeed, in populous districts patients have been deliberately removed from one address to another to avoid the medical officer of health and his staff, and this has only been discovered when it has been found necessary to call in a second medical practitioner who has notified the disease a second time. Again, in towns where measles is notifiable, a second practitioner has discovered the case to be one either of typhus fever or commencing small-pox; such cases should obviously be notified a second time.

We still find some medical officers of health desirous of reducing the fee for notification in those instances in which a second case of infectious disease occurs in a house where a previous one has been notified within a given time—some say a month. This proposal is based on the assumption that the medical officer of health has the premises under supervision by reason of the first notification. We are convinced that this reasonable view is quite inapplicable to a very large portion of England and Wales, and even where such supervision is maintained it is done by a sanitary inspector, who is quite incompetent to judge whether the second case occurring, say, two or three weeks after the first one is a case of the same disease or whether the same or different remedial measures are called for. We have so recently dealt with this proposal that we need only now refer to one other aspect of it. Since notification of infectious disease came into operation this country has taken a first step towards a national registration of disease, and from 1892 onwards use has been made of the information thus procured to study the relation of season both to the occurrence of certain specified diseases and to their fatality, the necessary data being annually compiled from the notification returns by the medical officer of the Local Government Board. But if the proposal here suggested were carried out the aim of those interested in preventive medicine would in this respect at once receive its death blow. A fatally retrograde step would be taken by the country which has always hitherto been foremost in the desire to place public health measures on a scientific footing, the object being to save a certain number of half-crowns. On this point alone, we believe, promoters of future legislation must be prepared for much opposition. It is also curious that this demand for a very mischievous little piece of economy should come from medical officers of health, for it is on their behalf that a weekly distribution of the amount of infectious diseases in a large number of districts of England and Wales is made. It was inferred that they wanted actual facts, not garbled ones; and the system was inaugurated by Dr. TATHAM because it was held to concern every district to know whether an adjacent one had five or fifty cases of a certain infectious disease.

"Ne quid nimis."

SCHOOL HYGIENE.

SCARCELY more than two hundred years have elapsed since the first efforts were made—and to their praise be it said, by the Scotch—to provide a public school for the education of children in every parish. A hundred years later England awakened to the necessity of supplying the means of elementary education, which up to that time had been limited to the grammar schools maintained by the endowments of pious benefactors. Successive acts of the legislature by limiting the age at which work was allowed to be commenced facilitated the spread of knowledge by affording time for instruction, but it was not till 1870 that through the institution of school boards, as effected by Mr. Forster's Education Act, education became truly general. In 1880 attendance was made compulsory, in 1891 education became free by the institution of the fee grant, in 1893 special education was decreed for the blind and deaf, and in the

Digitized by Google

same year, with very few exceptions, the age of exemption, below which no child is allowed to work, was raised to eleven. The Moral and Physical Aspects of School Hygiene, to which every child is now subjected, is the title of the Howard Medal Prize Essay of the Royal Statistical Society the author of which, Dr. James Kerr, is the medical superintendent of the Bradford School Board, and it is here shown how important in every point of view are the conditions of their environment to children during their school life. The accumulation of large numbers of children in limited spaces of course predisposes to trouble of various kinds. Infectious diseases are more likely to spread unless preventive measures are adopted, whilst the want of exercise and deficiency of pure air which exist might be expected to cause children to be an easy prey to such diseases in spite of being well fed and warmly clothed. The average attendances at the Poor-law schools in 1894 had risen to the high number of 4,225,000. The death-rates for each period of five years amongst girls, especially in the later years of school life (10–15 and 15–20), are found to be greater than amongst boys. With increased attendance at school deaths from accidents have decreased amongst boys, and in regard to infectious diseases, including measles, whooping cough, scarlet fever, and diphtheria, the statistics that Dr. Kerr has collected show that there has been no obvious bad effect but rather a good protective effect from school attendance. Small-pox, owing to the girls being more exposed by school attendance to the communication of infection, has somewhat increased, and so too has phthisis, and Dr. Kerr asks whether this effect can be owing to the atmosphere of the school being fouler than that of their own homes. Skin diseases, parasites, and infectious ophthalmia may be regarded as due to home influences. The greatest difficulty that presents itself at the present time in school hygiene is the question of warming and ventilation, and a curious calculation shows that greater efficiency is obtained when these conditions are good, since more grant is earned, and better work is done, as tested by examination results, by the well-nourished brains of the children in the mechanically ventilated schools. Dr. Kerr's dicta are that for the artificial ventilation of a school by warmed air 1000 cubic feet per hour per child should be the lowest estimate, the accommodation being reckoned at 10 square feet per child or 8 square feet for infants; that the velocity of the incoming air should not exceed 5 feet per second, entering through inlets allowing 13 square inches per child; and that the temperature of the room should be 60° F. and the differences between a wet and a dry bulb thermometer should not exceed 4° or 5°. From Dr. Reid's and Dr. Bailey's investigations it is certain that the ventilation of the schools is in a lamentable condition. In the rural district of Stafford Dr. Reid found that in thirteen of the eighteen schools the carbon dioxide exceeded 20 volumes in 10,000, and in four it was as much as 30 volumes, one school showing 37 volumes, the average proportion present in fresh air being, it will be remembered, 4 volumes in 10,000. It must not be overlooked that whilst the carbon dioxide is a serious impurity it is only an indication of the still worse contamination of the air by other emanations from the skin, lungs, and clothes of the children. Some interesting facts in regard to the hearing and the vision of school children are recorded by Dr. Kerr. In his concluding remarks, with the tenour of which every practitioner of medicine will agree, Dr. Kerr remarks that the hygienic study of ordinary school children is only beginning. The evil effects of the home, uninfluenced and too often neglected by other agencies, could, he thinks, to some extent be influenced by the medical inspector for good. Morally and physically the homes will be improved as the school children are accustomed and educated to clean, beautiful, and well-ordered schools and inspired with an abhorrence of hot, foul air and stuffy rooms, intolerance of diseased conditions and vermin, and, above all, a sense of powers that require mastery, a confident self-control, and a feeling of citizenship in this world, beyond which there is no other good to be desired by the State from its schools.

CENTRAL HOSPITAL COUNCIL FOR LONDON.

THE desirability of the existence of some body which should connect all the hospitals of London has long been recognised by all who have considered the subject of hospital administration. In the early part of the year the Charity Organisation Society suggested the formation of a central hospital board for London, and a committee was formed consisting of 168 members interested in hospital work, but it was felt that in such a matter as this the hospitals were chiefly concerned, and that it was very desirable that such a board should consist of representatives from the various hospitals. A meeting was accordingly held at Westminster Hospital of representatives from all the London hospitals to which medical schools are attached, and a committee was appointed to draw up provisional rules for the "Central Hospital Council for London." Each hospital was requested to nominate three representatives, one of whom must be a member of the managing body of the hospital and one a member of the medical staff; and as there are in London twelve hospitals with medical schools the new Council consists of thirty-six members. The first meeting was held on Nov. 16th at St. Thomas's Hospital, and the constitution and rules of the Council were arranged. The following are the representatives already appointed:—St. Bartholomew's Hospital: Sir Trevor Lawrence, Bart., Mr. Alfred Willett, F.R.C.S. Eng., and Mr. W. H. Cross. St. Thomas's Hospital: Mr. J. G. Wainwright and Mr. Henry Hugh Clutton, F.R.C.S. Eng. Guy's Hospital: Mr. Alfred Cohen and Mr. A. J. Lawrence, C.I.E. Charing-cross Hospital: Mr. T. P. Borrett, Mr. J. H. Hale, and Dr. Green. King's College Hospital: Viscount Dillon, the Rev. Prebendary Wace, D.D., and Dr. A. B. Duffin. London Hospital: Hon. Sydney Holland, Mr. J. H. Hale, and Dr. Stephen Mackenzie. Middlesex Hospital: Sir Arthur Watson, Bart., Q.C., Dr. Fowler, and Mr. F. Clare Melhado. Royal Free Hospital: Mr. Charles Burt, Mr. G. F. Sheppard, and Mr. Willmott H. Evans, F.R.C.S. Eng. St. George's Hospital: Mr. Timothy Holmes, F.R.C.S. Eng., Dr. Isambard Owen, and Mr. C. L. Todd. St. Mary's Hospital: Colonel Stanley G. Bird, Mr. Malcolm Morris, F.R.C.S. Edin., and Mr. Thomas Ryan. University College Hospital: Mr. Henry Lucas and Dr. J. Rose Bradford. Westminster Hospital: Dr. Allchin, the Rev. Dr. Troutbeck, and Mr. G. G. Tremlett.

THE PARISH NURSE DIFFICULTY.

JUDGING from the character of the correspondence now taking place in the columns of the *Newbury News* the subject of parish nursing is receiving much attention in Berkshire. In a recent letter certain views are expressed which are not likely to receive either the approval of the medical profession or of those who are most genuinely interested in the provision of nurses for rural districts. The writer, Miss Thoyts, of Suthampstead Park, recognises the fact that the labouring poor prefer the services of women taken from the same rank of life and who have received the requisite training. But, says Miss Thoyts, "what our poor people need are not merely parish nurses as the term nurse is now understood, but clever midwives capable of undertaking such cases solely on their own responsibility—in fact, women doctors, duly qualified and recognised as such, who will practice from rural centres, attending the women for a fixed fee, and working as professional nurses, not as paid charity servants." Not only, however, are the duly qualified women-doctors to act as parish nurses, "working among

Digitized by Google

their own sex," but they are to "tend both soul and body simultaneously and spread true religion both at home and abroad." The chief objection to such an arrangement is said to be the "doctor's jealousy of encroachment." After this we are not surprised to read an eulogy upon the prescribing druggist who "knows each person," who is "consulted as a friend," "explains what is in his medicine and why it is given," and last, but not least, "charges nothing for his advice." We are also informed that where parish nurses are engaged they are fast taking the place of the chemist. The change, however, in this respect is not considered to be for the best, for "the chemist is a man of experience," &c. This kind of advocacy is not likely to assist in promoting the interest taken by the profession in the provision of nurses for the deserving poor. If there is really a demand for lady-doctors in rural districts doubtless in time the demand will be met, but to expect the same person to act as medical attendant and as nurse, and to put up with "cottage fare and cottage furniture," is, to say the least unreasonable and absurd. The family washing is not referred to; possibly whilie residing in the cottages this will not be considered any part of the woman-doctor's duty. Whatever may be the case in Berkshire other counties are finding practical means of overcoming the difficulties Miss Thoyts refers to. In Essex the County Cottage Nursing Association has done such good work that, at the suggestion of Lord Rayleigh, the Lord-Lieutenant of the County, a Jubilee Fund was raised to still further increase its usefulness, and over £2000 have been raised and handed over to the association. In this county the cottage nurses are taught to consider themselves the handmaids of the medical practitioners, and are warned against taking any unnecessary responsibility. Were any of them to attempt to compete with the prescribing druggist doubtless their names would speedily be removed from the rolls of the association. Before attempting to commence work on the lines laid down by Miss Thoyts and courting certain failure Berkshire had better make itself acquainted with what is being done elsewhere. The problem is admittedly a difficult one, but the difficulties should not be insurmountable. The way to overcome them, however, is by acting in harmony with the wishes of the profession and not in attempting to set up a class of nurses who are at one and the same time to act as doctor, nurse, and district visitor.

MEDICAL OFFICERS OF HEALTH AND THE WATER-SUPPLIES OF THEIR DISTRICTS.

THE unfortunate experience of Maidstone has taught us many lessons, and not the least important of them has been that which shows the necessity for a constant supervision of the sources from which water-supplies are derived. This Maidstone catastrophe should have the effect of inducing medical officers of health throughout the country to inspect, or at least to attempt to inspect, the water-supplies of their districts and to report thereon to their sanitary authorities. In some cases there may obviously be considerable difficulties in carrying this out, but it is only in this way that a medical officer of health can relieve himself of responsibility with regard to the future and place such responsibility upon the shoulders of the district councillors. It may be that certain medical officers of health will have their proposals for reform and control disregarded, but in such cases the officer has done his duty; he has placed on record the actual condition of affairs, and with those to whom is entrusted sanitary administration rests the moral responsibility. As an example of the attitude which we suggest a recent special report upon the water-supply of Chatteris, which has just reached us, may be mentioned. Mr. Ronald Daniel, the medical officer of health of the district, discusses the water-supply from the chemical and bacteriological, as well as from the topographical standpoint, and from whichever view the subject is approached there would seem to be ground for anxiety. Chatteris, like many other towns of its size, draws its water from shallow wells situated in a pervious formation overlying clay which is also riddled with other holes for the deposition of excremental matters. The history of Chatteris shows, as also does the history of many another place, that it has in no wise been remarkable in the past for the prevalence of water-borne diseases, but Mr. Daniel points out how that the conditions which obtain are such that an explosion might occur at any moment. Polluted water might, he tells the district councillors, be consumed for years with impunity, but on the other hand disastrous results might at any moment follow. The report concludes thus, "The public safety, gentlemen, lies in your hands and, having placed the several facts of the matter before you, it is for you to decide whether you will augment such safety or in the future run those risks which so far have happily been evaded." There is a healthy and vigorous ring about these words, and many other medical officers of health will do well to approach their sanitary authorities in a similar strain. Let the facts be placed on record so that they may be referred to if a day of reckoning comes.

MEDICO-LEGAL ENTOMOLOGY.

DR. WYATT JOHNSTON and Dr. George Villeneuve have published in the August number of the *Montreal Medical Journal* some valuable researches on the entomology of dead bodies, a branch of scientific inquiry originated a few years ago by M. P. Mégnin, of Paris, whose book, "La Faune des Cadavres," was reviewed in THE LANCET of Oct. 24th, 1896, p. 1157. The result of M. Mégnin's work is of considerable interest and importance in a medico-legal sense from the fact that the date at which death occurred may be estimated from the insects and the insect débris found in a decomposing body. The greater part of the available evidence has naturally been collected in Paris, but it is obvious that the circumstances will vary in different countries. The observations of Dr. Johnston and Dr. Villeneuve were made in the vicinity of Montreal, where the temperature from the beginning of October to the end of April is much lower than in Paris. According to M. Mégnin the fauna of bodies exposed to the air is as follows: While the body is still fresh it attracts the diptera Musca, Cyrtoneura, and Calliphora. After decomposition has set in the flesh flies Lucilia and Sarcophaga are attracted. Later (from the third to the sixth month), when fatty acids are formed, the body is invaded by the beetle Dermestes and by the moth Aglossa (this latter was never met with in the Canadian observations, but is apparently very common in France). Later, Pyophila of the diptera and Necrobia of the coleoptera appear as the condition becomes caseous. After this (from the fourth to the eighth month) comes a period of ammoniacal decomposition marked by liquefaction of the tissues into a blackish pulp, during which stage a group of coleoptera, Necrophorus, Silpha, Hister, and Saprinus are met with, as well as the diptera Ophira, Thyreophora, Phora, and Lonchea. In the next stage (from the sixth to the twelfth month) the tissues dry up and are invaded by acari, the débris and excrement of which form a powdery deposit. Subsequently (from one year to three years), with the progressive drying of the the tissues, Aglossa (second generation) reappears, together with the moth Tineola and the coleoptera Attagenus and Anthrenus. Finally (over three years), when nothing but the dried ligaments remain on the bones, two forms of coleoptera, Tenebrio, and Ptinus appear and devour these. In the case of buried bodies the fauna are said to be much

Digitized by Google

less varied and to consist mainly of Phora and Ophira in the diptera, and Philonthus and Rhizophagus of the coleoptera, together with any diptera which may have gained access to the body before burial. This list shows that only a small number of genera are represented out of the total diptera, coleoptera, acari, and lepidoptera occurring in France, so that in practice their recognition becomes comparatively easy. Dr. Johnston and Dr. Villeneuve found in their observations that the order of the successions of the different insect forms followed the rules laid down by M. Mégnin, but they occurred on exposed bodies in a shorter time than he stated. Of the twenty-three genera indicated by him as characteristic of exposures up to one year they met with eleven, and five of the twelve remaining are rare on the American continent. They only encountered two which he did not mention. These were Trox and Omosita, both rare in France, although necrophagous. A knowledge of the period of the year at which breeding of the different insect forms takes place is of the utmost importance in determining the dates. A deduction not mentioned by M. Mégnin, but which the Canadian observers repeatedly found of practical use, is that if empty dipterous puparia are present the date of exposure may be reckoned as not less than one month, while the absence of empty puparia indicates an exposure of not over one month in warm weather. Their observations agreed with those of M. Mégnin as to the order of the successions. Thus, wherever acari were found it was evident that Silpha and Hister had preceded them. Pyophila was only seen when saponification of the fat was well marked. Dermestes was seen earlier in the saponification period, but never in the preliminary decomposition. Calliphora and Lucilia were the forms met with up to the end of the first month in cases where the dates were accurately established. Where the exposure lasted for only a few days Lucilia was absent. Dr. Johnston and Dr. Villeneuve give particulars of two cases of discovery of decomposed bodies in which the entomological method was confirmatory of other evidence as to the date of death; there was a third case, however, in which the body of an infant hidden over a kitchen ceiling—for five weeks as was supposed—nevertheless contained insects which are not usually found under a period of three months. The material facts were not established and the prisoner was acquitted. In conclusion, the authors recommend that observations and experiments upon exposed human bodies should be made in the particular locality before the present entomological data are applied to legal medicine. Experiments with animal bodies other than human are apt to be misleading, and results obtained by such means have not very much significance.

THE MICROSCOPE IN EXAMINATION OF PLEURITIC EFFUSIONS.

THE microscopic examination of pleural and peritoneal effusions for the purpose of establishing the diagnosis of new growths of these membranes before a clinical diagnosis can be determined is a diagnostic measure but rarely instituted. Much has been done with the chemistry of these fluids, but few careful investigations have been reported of the cellular constituents in those cases in which malignant tumours of the pleura or peritoneum were present. A paper by Dr. Aldred Scott Warthin in the *Medical News* (Philadelphia) for Oct. 16th is a valuable addition to our knowledge on this subject. He asks one question, "To what extent is it possible for the examination of the cellular elements of effusions to establish the diagnosis of new growth of pleura or peritoneum?" As an answer he gives his own experiences and methods of procedures and several illustrations of the varieties of cells met with in serous effusions. The fluid should, of course, be placed in a centrifugating machine and the deposit be examined under a fairly high power of the microscope. Dr. Warthin sums up his conclusions thus: 1. In all doubtful cases, when fluid can be obtained by exploratory puncture, cover-glass preparations should be made by fixing in absolute alcohol and ether. This should be done immediately after the withdrawal of the fluid in order that the mitoses may be preserved. 2. In early cases of simple pleurisy the sediment contains endothelial cells and no fibroblasts. The endothelial cells may be desquamated in large pieces. 3. In fibrinous pleurisy, tuberculous or septic, the sediment contains, in addition to endothelial cells, numerous fibroblastic forms. In later stages, when adhesions are forming, the endothelial cells may be entirely absent and only fibroblasts may be found. 4. In the diagnosis of sarcoma of serous cavities the character and number of the cells and the presence of numerous mitoses are the points upon which the diagnosis must be based. It is, of course, evident that the quickly-growing soft forms of sarcomata are the ones most apt to lead to the presence of cells in the fluid. The tendency of all sarcomata to break down after reaching a certain growth makes it extremely likely that in most cases free cells will be found. The diagnosis of spindle-celled sarcoma is easy from the occurrence of large numbers of spindle cells of similar size and shape, showing fewer branching processes than fibroblasts and containing more mitoses. In the round-cell forms the tumour cells are to be distinguished from the endothelial cells by their size, the character of the nucleus, and the relation of the nucleus to the protoplasm. The presence of mitotic forms will again be the most important point; in the small round-celled sarcoma these are not so easily seen. The greatest difficulty will be in the differentiation of the cells of a polymorphous-celled sarcoma from the fibroblastic forms found in fibrinous exudates. And from the general character of cell and nucleus the presence of division forms must in all cases be looked upon as being the most important point. In conclusion, therefore, the presence of numerous cell-division forms in the cells of the sediment of serous exudates may be taken as strong (perhaps conclusive) evidence that the effusion is due to the presence of a new growth, inasmuch as mitoses are but rarely found in the cells of purely inflammatory exudates.

A HOSPITAL MASONIC LODGE.

THE Masons of St. Mary's Hospital, London, are to be congratulated upon the way in which the consecration of their new Lodge, No. 2668, passed off at the Freemasons' Hall last Monday. The consecration was performed in an impressive manner by the Pro-Grand Master, the Earl of Lathom, by the authority of, and under the warrant issued by, H.R.H. the Prince of Wales, who has graciously consented to act as Worshipful Master of the Lodge, the "Sancta Maria," during the coming year, appointing the senior surgeon of the hospital, Mr. Edmund Owen, P.M., to act as his deputy. In the course of the ceremony the Rev. Studholme Brownrigg, past grand chaplain, gave an interesting address upon the close affinity which has always existed between members of the medical profession and the craft of Masonry, and paid a high tribute to the zeal and unselfish kindness with which medical men, whether Masons or not, were always ready to help in the relief of human suffering. After the consecration Brother Owen was installed deputy master of the "Sancta Maria" by the Earl of Euston, assisted by Viscount Dungarvan. A telegram addressed to the Deputy Master, and signed "Albert Edward," was read wishing a successful career to the Lodge. After the closing of the Lodge the brethren adjourned to a banquet, at which 120 covers were laid. In the course of an eloquent speech

Digitized by Google

by Lord Lathom wishing success to the "Sancta Maria," he said that he was a firm supporter of "class-lodges" in that they brought the young and the old together and helped to consolidate them in good work and in spreading amongst those just entering a profession a knowledge of the interesting and beneficent craft of Masonry. We hope to give on a future occasion, when pressure on our space is not so great, a list of the first officers of the Lodge. Meanwhile we offer to the Deputy Master, the Wardens, and the Brethren of the "Sancta Maria" our congratulations on the success of the inauguration of their Lodge.

PORTAL THROMBOSIS WITH SYMPTOMS OF INTESTINAL OBSTRUCTION.

PORTAL thrombosis is difficult of diagnosis, the symptoms being usually like those of cirrhosis of the liver, of which, indeed, it is often only a complication. The following case—in which they were acute and of a very different type, resembling at first those of biliary colic and then those of acute intestinal obstruction—is exceptional. It is published by Dr. Barth in the Proceedings of the Socié é Médicale des Hôpitaux of Oct. 28th, 1897. A robust man, aged forty-seven years, of intemperate habits, was suddenly seized with violent epigastric pain and vomiting. The symptoms recurred in crises lasting several hours every day, which yielded only momentarily to morphine. Examination showed slight tenderness in the epigastric and right hypochondriac regions. The bowels acted regularly. Suddenly, on the seventeenth day, a change took place. The abdomen became tympanitic, hiccough and abundant vomiting of green porraceous matter occurred, the patient became feverish, and his expression altered. On the next day the temperature was 104·5° F., the pulse 140 and thready, and the vomiting continual; the abdomen was uniformly distended tight and very tender; the eyes were sunken, the voice was broken, and the expression was hippocratic. There had been no passage of fæces or flatus for twenty-four hours. Internal strangulation complicated by acute peritonitis was diagnosed, and laparotomy was proposed; but the patient became rapidly weaker and died in a state of collapse. A necropsy was made. The abdomen contained some reddish serum. The intestines were uniformly distended and the peritoneum was injected, of a bright red colour, but without exudation, except at a loop about the middle of the jejunum, which was purple, almost blackish, like a strangulated intestine, and covered with false membranes. The mesenteric veins not only of the diseased, but of the healthy, intestine were thrombosed throughout. In the portal vein thrombosis was more marked, the clot was greyish-red, firm, elastic, and manifestly older than the mesenteric. The thrombosis was not prolonged into the intra-hepatic divisions. The liver was diminished in volume and flabby; it was not cirrhosed or otherwise diseased. The question arises—Was the thrombosis the cause of the intestinal lesions, or were the latter the primary? Might there not have been a temporary strangulation of the intestine which caused incipient gangrene, then mesenteric thrombosis, and, finally, peritonitis by permitting migration of colon bacilli through the disorganised intestine? To this view there are several objections. No trace of constriction or mesenteric torsion was found. Above the diseased loop were analogous lesions less advanced and becoming slighter from below up. The intestinal lesions were too recent to explain the preliminary symptoms. Finally, the portal thrombosis was evidently much older than the mesenteric. Again, why was there gangrene of only a limited portion of intestine from this generalised portal thrombosis? Dr. Barth cites a number of such cases in which the thrombosis extended to the whole length of the intestine, in which only a limited lesion—cyanosis with sanguineous infiltration or gangrene, was found. In all the symptoms simulated acute obstruction and a similar part was affected—near the middle of the jejunum. He suggests an anatomical explanation—probably there is complete absence of anastomotic communications in this part which is situated in the centre of the mesenteric system, but above and below some collateral circulation by means of parietal veins is possible. In the Transactions of the Pathological Society of 1876, page 124, the late Dr. Hilton Fagge published a very similar case to Dr. Barth's, in which even the same doubt as to intestinal strangulation arose at the necropsy. But as a type, pathological and clinical, this condition has not been described.

THE GENERAL INFIRMARY AT LEEDS.

THE new operating department has been completed and is now being used regularly. There are two theatres, and each theatre has its separate waiting- and anæsthetic-rooms communicating by double doors. On either side of the entrance-hall are two rooms, one a recovery-room, the other a private room for the surgeons. The whole is lighted by electricity and supplied with warmth and washed air on the "Plenum" system. The floors throughout are constructed of terrazzo, and slope towards a gully so as to allow of easy flushing. The walls of the theatres and instrument-room are of opaline of a light green colour, fixed in large slabs to avoid joints as much as possible. A novel feature is the continuous supply of hot and cold distilled water in addition to the ordinary service. The instrument cupboards which are placed in a room connecting the two theatres are of the newest available pattern, and made of glass and gun-metal. The operating-tables are of metal enamelled white. The dressers' and sisters' tables are of white metal and glass. All the windows are fixed and cannot be opened. For warmth and ventilation full reliance is placed upon the "Plenum" system. The temperature in the two theatres is easily maintained at 65° F. The heating of the whole department takes twenty minutes. The arrangements for sterilising instruments consist of copper "fish-kettles," electricity being employed for the heating of the water. The woodwork, students' galleries, &c., are of polished teak.

THE VALUE OF HYDROCHLORIC ACID IN SCIATICA DISCOVERED BY ACCIDENT.

A SOMEWHAT remarkable instance is recounted in the *Semaine Médicale* of a patient having arrived at a successful method of treatment for himself by the merest accident—an accident, too, which was founded on a blundering ignorance of chemistry. A man who had suffered for many years from sciatica was treated in an Algerian hospital by means of hypodermic injections of salt and water, but without much success. After he had left he bethought him that perhaps the salt was not strong enough and that a stronger preparation of salt might be more successful. He therefore procured some "spirit of salt" (hydrochloric acid) and painted it on the skin, getting rid of his long-standing trouble in a few days. Having occasion shortly afterwards to attend the hospital for some other affection he confided in Dr. Bourlier, professor of therapeutics, whom he saw, how he had managed to get rid of his sciatica. This gentleman thought the plan worthy of trial, and employed it in several cases with invariable success. He then told his son, Dr. Maurice Bourlier, who was house physician, and he treated a number of cases with great satisfaction to himself and to his patients. A thesis has recently been published on the subject by Dr. C. Gennatas, of Montpellier, on the basis of a dozen cases of neuralgia of the sciatic nerve, all of which were completely relieved by this means. The procedure is simple enough. Half an ounce of strong hydrochloric acid is put in a small

Digitized by Google

cup and a brush is dipped in it and applied over the painful part of the nerve, three or four coats being painted on. The limb is then enveloped in a cotton-wool dressing. Of course, the application causes a somewhat severe smarting sensation, but this is quite bearable. A few minutes afterwards the skin becomes reddened and hot, and sometimes bullæ are formed which fill with fluid. These even if they occur disappear in two or three days. Usually the patient feels better even after a single sitting. The application can be repeated in from twenty-four to forty-eight hours, but not again for several days for fear of producing sloughs. Of course, too, where there are bullæ they must be avoided in subsequent applications. No serious inconvenience is caused by the hydrochloric acid such as was experienced when a similar procedure was attempted some years ago by Dr. Legroux with strong sulphuric acid, which was found to be liable to cause extensive sloughing of the skin. The twelve patients referred to were all reported as cured in from three to five sittings extending over from a week to twenty-five days. It may be well to say that the hydrochloric acid of the French Codex is very slightly stronger than that of our own Pharmacopœia.

THE JUBILEE MEMORIAL AND THE CITY OF BRISTOL.

THE city of Bristol is to be heartily congratulated on the success of its scheme for worthily commemorating the Diamond Jubilee of Her Majesty Queen Victoria. In February last the inhabitants resolved to provide a convalescent home chiefly for the use of the patients of the Royal Infirmary and the General Hospital, but partly also for the use of other convalescents. The original proposal was to raise £50,000—£20,000 for the building and £30,000 as a nest egg in the form of endowment. This generous conception has been exceeded, thanks chiefly to the cordial and munificent gifts of some of the leading citizens, especially Messrs. Fry and Messrs. Wills and Co. The subscriptions from gentlemen connected with the latter firm include £5000 from Sir William Henry Wills, £10,000 from Mr. H. O. Wills, and the promise from Mr. E. P. Wills to provide a building in concert with the committee of the value of £20,000. Mr. Joseph Storrs Fry gives £10,000. In spite of the competition of numerous other Jubilee objects the total amount promised up to the present date is £80,000. It will be gratifying to Her Majesty to know that the sentiments of her grateful subjects in Bristol have taken such admirable shape. A convalescent home for generations to come is a form of gift which for grace and usefulness cannot be exceeded. Bristol has done well.

WOUND OF THE BRACHIAL PLEXUS: SUCCESSFUL SECONDARY SUTURE.

THE following case is recorded in the *Intercolonial Medical Journal of Australasia* of Sept. 20th, 1897, by Dr. Humphrey Martin. A man was cut with an axe along the posterior border of the left sterno mastoid muscle. The wound commenced one and a half inches above the clavicle and ran upwards and backwards for two inches. The surgeon who was called said that it was one and a half inches deep and had divided the nerves, but he only sutured the margins of the wound. Sensation was lost over the lower left side of the occiput, the lower anterior triangle of the neck, and the area supplied by the descending cervical nerves, the outer side of the arm and of the extensor surface of the forearm, and the thumb and index fingers. At first the arm was useless, but a month afterwards the patient could flex and extend his fingers and move his thumb, but the muscles of the forearm were wasted. There was complete paralysis of the deltoid, biceps, coraco-brachialis, brachialis anticus, triceps, and scapular muscles. The pectorals were very weak. Supination and pronation of the forearm were very defective. The flexors and extensors of the wrist and fingers acted well to faradaisation, as did also the serratus magnus, infra-spinatus, and rhomboidei. The deltoid, supra-spinatus, pectoralis major, biceps, triceps, coraco-brachialis, brachialis anticus, and supinator radii longus gave no response. To the constant current the muscles supplied by the median nerve reacted when one rheophore was placed over the scar and one on the muscles, but not those supplied by the supra-scapular, circumflex, musculo-cutaneous or musculo-spiral nerve to the triceps. It was concluded that the cord formed by the union of the fifth, sixth, and seventh cervical nerves, just above where the supra-scapular nerve comes off, must have been divided. On the fortieth day after the injury a three-inch incision down to the posterior border of the sterno-mastoid was made, dividing the platysma and the deep cervical fascia. Some small nerves, probably the descending cervical, were seen. These were pulled backwards and by carefully deepening the wound the distal end of the cord mentioned was found. The proximal end which was slightly bulbous was found half an inch above this. The ends were trimmed and united by kangaroo sutures. Some recovery of motion and sensation was evident soon after the operation, and this steadily increased until the patient had a useful arm. When last heard of he had recovered power in all his muscles except the deltoid which was improving, and he had regained sensation except in the area supplied by the circumflex nerve.

ACUTE AORTITIS AS A COMPLICATION OF FACIAL ERYSIPELAS.

THOUGH infective endocarditis is one of the recognised complications of erysipelas the very similar lesion, acute arteritis, is almost unmentioned in medical literature. Moreover, our present knowledge that the former complication is due to infection of the endocardium would lead us to regard the latter as a possible result of the same process. As long ago as 1867 Ponfick called attention to endarteritis, principally of the aorta and of the circle of Willis, in erysipelas; he considered it almost constant and described the lesions, especially histologically. His views appear to have been unconfirmed and forgotten until quite recently, when MM. Thoinot and Griffon brought the subject before the Société Médicale des Hôpitaux and read notes of the following case. A woman, aged fifty-three years, entered hospital about a month after an attack of facial erysipelas, from which she had not properly convalesced. General weakness, difficulty of breathing, insomnia, and constant headache remained. On the second day a relapse of the erysipelas occurred, but only in the form of a small patch on the face. But the dyspnœa increased and became even agonising, and the temperature rose to 104·4°F. There were no signs of pulmonary disease to account for this, but a diastolic aortic murmur was heard. She became convalescent a second time, but soon the symptoms again appeared and also albuminuria, œdema of the legs, and lancinating pains in the sternal region. The symptoms increased in severity, the urine became suppressed, and finally she died, about two months after the onset of the relapse of the erysipelas. A necropsy showed considerable dilatation of the aorta and two kinds of lesions—recent acute arteritis of the arch engrafted on old atheroma. The former was characterised by rounded fibrinous deposits of variable size, more elevated in the centre than at the margins, of an amber colour. Microscopic examination showed all the appearances of acute inflammation of the aorta, in addition to those of atheroma. There was a sero-fibrinous effusion in the right pleura. The kidneys

Digitized by Google

showed signs of acute inflammation. MM. Thoinot and Griffon point out that the diagnosis of acute aortitis might have been made clinically from the murmur, the agonising presternal pain, and the dyspnœa which was unexplained by any signs of disease in the lungs. No doubt the atheroma was a predisposing cause of the acute inflammation, just as old cardiac disease predisposes to infective endocarditis, as was shown in THE LANCET of Sept. 25th, 1897.

MIDWIVES IN ALGERIA.

MADAME CHELLIER, to whose good work as a medical pioneer in Algeria we recently alluded,[1] has succeeded in establishing three French midwives in different parts of that country, and already their services are said to be highly appreciated by the native population. Of course three midwives are but as a drop in the ocean; but small beginnings often make big endings, and it is Madame Chellier's intention to found seven more midwifery posts in the province of Constantine, four in that of Algiers, and two in Oran. As a writer in a Parisian medical journal observes: "The unanimity with which the natives of all ranks have accepted the introduction in their midst of foreign residents and given them the *entrée* of their most private apartments is the best guarantee for the success of this philanthropic enterprise."

CITY COMPANIES AND HOSPITALS.

A LETTER appeared in the *Morning Post* of Nov. 15th which ran as follows:—

To the Editor of the Morning Post.

SIR,—I think it is not generally known that four of the twelve chief City Companies have agreed to open and endow a ward of thirty beds at St. Thomas's Hospital in memory of the Queen's Diamond Jubilee. As this means an expenditure of at least £2500 a year I think these City guilds have done well, besides the thousands a year they grant to all London hospitals.—Yours, &c.,

Nov. 13th. CITIZEN.

We are sorry to say, however, that the authorities of St. Thomas's Hospital inform us, in reply to our inquiries as to the matter, that no such action has been reported to them. We sincerely hope that at no very distant date the treasurer of St. Thomas's Hospital may be advised of such action which would not only be a worthy memorial of the Diamond Jubilee but also in thorough accordance with the traditions of the great City companies.

FACIAL NEURALGIA.

AT the recent meeting of the Association of German Naturalists and Physicians reported in the *Neurologishes Centralblatt*, an important discussion took place on this subject. Dr. Böttiger, of Hamburg, read a paper, in which he divided pains occurring in the region of distribution of the fifth nerve into four varieties, neuralgic, neuritic, psychical (or hysterical), and rheumatic. He insisted especially upon the clear distinction between the first two varieties, more particularly in reference to their etiology. Whilst neuritic pains were the result of toxic conditions or infective disease, neuralgic conditions were most frequently the result of local conditions, especially local chills. Treatment for such neuralgic conditions must as a rule be symptomatic. But in certain cases no doubt general hygienic and dietetic conditions—treatment by drugs and by mechanical and physical measures and also by electricity—were effective. He recommended in recent cases, especially occurring in young children, treatment by such means, but was of opinion that old-standing cases, especially in patients of advanced years, were only amenable to surgical measures. In the discussion which followed Dr. Bruns, of Hanover, said that he regarded the distinction between neuritic pain and neuralgic pain as an artificial one, for many of the severest neuralgias were determined by sclerosis of the blood-vessels of the nerves. He thought that there were certain cases in which the pain came in the second and third divisions of the fifth nerve in old people and was especially excited by eating and speaking, in which any treatment except surgical was useless. Dr. Rump, of Hamburg, agreed to some extent with Dr. Bruns. He had, however, known of one case in which operation failed to cure, but which was permanently relieved by the use of galvanism.

[1] THE LANCET, Sept. 18th, 1897, p. 734.

A NEW RESEARCH INTO THE MUSCLES OF RESPIRATION.

RUDOLPH FICK publishes in his *Archives of Anatomy and Physiology* a paper on the Muscles of Respiration which well repays perusal. In the first part of his paper he refers to the results of other investigators especially in relation to the intercostal muscles, but the latter part is an account of his own original investigations. The observations of other investigators have all been made with the internal intercostal muscles dissected, and their action determined by direct inspection. In those of Dr. Fick all the costal muscles were left intact. He first examined the auxiliary muscles of respiration in the neck and proved that they were absolutely inactive in normal quiet respiration and only came into action in isolated extraordinary, deep, sighing respirations, the result of their action being to elevate the thorax *in toto*. Next the auxiliary muscles of respiration and the diaphragm were paralysed by severing their nerves in the neck, and the action of the abdominal muscles eliminated by dividing them. It was then found that the respirations continued in normal rhythmic manner, the difference between inspiration and expiration (apparently active) measured through a tracheal cannula being 66 mm. of water. These experiments taken in connexion with the geometrical deductions contained in the early part of the communication proved that normal quiet inspiration is the effect of the contraction of the external intercostal and intercartilaginous muscles, and that expiration is effected by the internal intercostal muscles. Bergerdal and Bergmann in Stockholm have arrived at the same results by similar experiments.

THE annual dinner of the staff and past and present students of the Dental Hospital of London will be held on Saturday, Dec. 4th, at the Hôtel Métropole (Whitehall Salon), under the presidency of Mr. A. S. Underwood, M.R.C.S. Eng., L.D.S. Gentlemen either now or formerly connected with the hospital or medical school who may through inadvertence not have received special notice and who may desire to be present are requested to communicate with the Dean at the Dental Hospital, 40, Leicester-square.

A BREAKFAST meeting of the British Medical Temperance Association was held at the Cannon-street Hotel at 8 o'clock on Thursday morning, Nov. 18th, 1897. Dr. Barlow and Mr. Victor Horsley addressed the meeting.

DR. J. BEAN BRADFORD, the Brown Professor, will deliver two lectures on Atrophy and Hypertrophy of the Kidneys at the University of London on Nov. 23rd and 30th.

THE Buchanan Medal of the Royal Society has been awarded this year to Sir John Simon, and the Davy Medal to Dr. J. H. Gladstone.

THE first lecture in connexion with the Jacksonian Lectureship, founded by the Neurological Society in honour of Dr. Hughlings Jackson, will be delivered by him at

11, Chandos-street, W., on Wednesday, Dec. 8th, 1897, at 8.45 p.m.

WE deeply regret to announce the death of Dr. James Cagney, which took place yesterday (Thursday) morning. Dr. Cagney was suffering from typhoid fever and succumbed to sudden cardiac failure.

LEICESTER AND SMALL-POX.

IN connexion with small-pox and vaccination so much has been heard of Leicester and the "Leicester method" that the publication of Dr. Sidney Coupland's report to the Royal Commission on Small-pox in that town ought to be welcome alike to medical men and to politicians. Up till now the main sources of information regarding Leicester and its doings have been anti-vaccinationist. A large number of witnesses were sent up by Leicester to the Royal Commission, and one of these, Mr. J. T. Biggs, was in the witness-box for many days. The *Vaccination Inquirer*, also, has for years past dealt very freely in statements regarding Leicester, and the country has been stumped by orators proclaiming the virtues of the Leicester method. The present report by a thoroughly competent recorder of observed facts, appointed specially by the Commission to make an inquiry into the Leicester outbreak of 1892–93, affords the first opportunity of checking some of the statements and is of great value notwithstanding that the facts recorded occurred five or six years ago. Needless to say the report is not newly written though it is newly published.

In the first place it is necessary to be quite clear, or as clear as may be, regarding what is, and what is not, the Leicester method of dealing with small-pox, and here, to avoid if possible charges of misrepresentation, it will be well to take as our authority leading supporters of the method. Mr. Biggs stated[1] that when a case of small-pox is reported an inspector immediately visits the infected house, endeavours to ascertain where the disease was contracted, where the patient has been working and visiting, and his movements generally for ten or twelve days previously. All persons who have visited the infected house are seen and all factories and workshops where other members of the family have been employed are visited. Immediately on removal of the patient the house is fumigated with sulphur, liquid disinfectants are freely used in the drains and about the yard, and the ashpit is emptied and disinfected. Next day the bedding is treated by the hot-air process in a disinfecting chamber. An endeavour is made to prevail on all persons who have been connected with the infected house to go into quarantine, but "compensation for loss of time is *not* offered." Quarantine is carried out at the hospital in a building near the small-pox wards, and "this period of rest is made to be of so pleasant and agreeable a character that at its expiration many have been reluctant to leave the hospital." But, above all, there is no compulsion. A considerable number have refused quarantine and have taken their own way. Also it is strenuously denied that vaccination forms any part of the method. Mr. Biggs says: "During the sixteen years from 1874 to 1889 inclusive no fewer than thirty-three importations—mostly from well-vaccinated districts—and a large number of successive outbreaks of small-pox were successfully STAMPED OUT. The town was thus saved from the further spread of the disease, with its possible ravages, by the LEICESTER METHOD of treatment *without recourse to vaccination*, and also without the slightest appeal to arbitrariness on the part of the authorities or any infringement of personal liberty."

A Special Commissioner who reported to THE LANCET in 1886 had stated otherwise as regards vaccination being a part of the method. He wrote that "all the persons in the house of the patient are vaccinated or re-vaccinated." In justice to Mr. Biggs we quote his reply, at the same time noting that our Commissioner visited Leicester in the earlier part of 1886, and that he was writing not of the future but of the past. Mr. Biggs said "Of fifty-five persons who voluntarily went into quarantine during the three years 1886–88, only twelve were vaccinated or re-vaccinated whilst in quarantine. If to these twelve we add three others who underwent the operation immediately before entering the hospital, there remain forty persons, or 72·7 per cent. of the above fifty-five who were neither vaccinated or re-vaccinated during the quarantine period." Now it happens that of these fifty-five, two, and two only, had been quarantined *previously* to our Commissioner's visit, and that both of these had been also re-vaccinated. That was in 1886. In 1887, of fourteen persons quarantined, it appears from a table submitted by Mr. Biggs to the Vaccination Commission, that seven were vaccinated in connexion with their quarantine. In 1888, however, only six of thirty-nine were so vaccinated. Mr. Biggs gave no information as to how many of the persons who were not vaccinated at the time of their quarantine had previously had small-pox, nor how many consisted of vaccinated children or re-vaccinated adults. At the time in question, be it remembered, vaccination of infants was not neglected in Leicester as it is now. In the fourteen years 1872–85, the average rate of neglect (children "not accounted for") was under 21 per cent. Almost certainly, therefore, many of the quarantined did not require vaccination and, needless to say, our Commissioner would have that in view in making his statement as to the practice previously to his visit in 1886. Very likely, however, some of those who were quarantined in 1887 and 1888 did require vaccination and were not vaccinated. But what has that to do with our Commissioner's statement?

It was *after* he had made his report, *after* public attention had been called to this feature in the dealings of Leicester with small-pox, *after* the Leicester anti-vaccinationists (some of whom, including Mr. Biggs, were also members of the sanitary authority) had been put on the defensive, that these persons were quarantined without being also vaccinated. Our Commissioner was not prophesying as to what course would be taken with regard to the vaccination of quarantined persons after his report had been published. The medical officer of health, who would naturally be acquainted with the Leicester practice both of his own time and of his predecessor's, wrote as follows in his report for 1886:—"Small-pox: The one case met with was in the person of an artisan. ..... The usual prompt measures were adopted; the patient was removed to the small-pox wards, and two other persons who had been in contact with him were subjected to fourteen days' quarantine and were re-vaccinated. ....." These were, it would appear, "the usual prompt measures." What then has Mr. Biggs's statement regarding 1887 and 1888 to do with the statement made by our Commissioner in 1886? Obviously nothing. Yet a connexion had to be established and here is how the Leicester anti-vaccinationist forges the bond of union. The italics are ours. "*Applying the same percentage to the 128 persons quarantined before 1886*, we find a further number of 35 persons who voluntarily submitted to the operation, who, when added to the other 15, make only 50 for the extended period. Thus, out of a total of 183 persons who had passed through the quarantine wards since the introduction of this system in 1877, *no fewer than 133 were neither vaccinated nor re-vaccinated whilst in hospital.*"

Here, then, Mr. Biggs discloses the origin of his statement regarding the 133. The disclosure was published in November, 1892. But what had he previously told the Royal Commission? After having dilated on the iniquity of THE LANCET and its Commissioner he says (June 10th, 1891): "The total number of persons who have been placed in quarantine since this method was introduced in 1877 is 183, and of this number 133 were neither vaccinated nor re-vaccinated either immediately before entering or whilst in the hospital. I think that this fact thoroughly disposes of the statement which has been made in regard to the compulsory vaccination and re-vaccination of all persons taken into our quarantine wards." Passing by the fact that our Commissioner, instead of speaking of compulsory vaccination and re-vaccination, had distinctly said, "Actual legal powers do not exist," and had explained that pressure could be applied without such powers,—passing by this fact, let us note what Mr. Biggs gave as the origin of his statistics, 183 and 133: (Q. 16,443) "That statement is based upon private information from the medical officer? *Yes; upon private information from the medical officer and from the sanitary inspector.*" (The italics are ours.)

It was in this manner that Mr. Biggs endeavoured to discredit before the Royal Commission THE LANCET Commission of 1886. But in the end of 1892 he states, not to

[1] Vaccination Inquirer, November, 1892.

Digitized by Google

the Commission, but in the pages of the *Vaccination Inquirer*, that his figures were obtained as we have above quoted—by a calculation based on the experience of only the last three years of the period, all but two of the cases having occurred after our Commissioner had written his article in our pages. We think it best to state these facts without comment of any kind. Comment, indeed, would be superfluous.

Mr. Biggs also fell foul of THE LANCET Commissioner with regard to the vaccination of the sanitary and hospital staff. He said: "The assertion that on the occurrence of small-pox the officials brought into contact with the case—the medical officer of health, the inspectors, the matron, and nurses at the hospital—are all vaccinated or re-vaccinated, applies to ten persons. They were in office when THE LANCET agent visited the town. Four of these not having been vaccinated since infancy and one not for nineteen years, the term of their 'protection' has theoretically expired." Needless to say, our Commissioner neither said nor suggested that these officials were vaccinated or re-vaccinated "on the occurrence of small-pox'—sometimes repeatedly in a single year in Leicester—and Mr Biggs knows perfectly well that neither THE LANCET nor any other responsible authority has suggested such frequency of repetition of vaccination Without attempting to judge between our Commissioner and Mr. Biggs, we will assume that an interval much too long for safety really had elapsed since the vaccination of five of the staff. Indeed, Mr Biggs is rather supported here by what Dr. Coupland ascertained regarding the hospital staff at the time of the outbreak of small-pox in 1892-3. At that time there were six members of the staff who had refused re-vaccination, and thirty-four who were looked on as already protected against small-pox, a few of them by having had small-pox, but all the others by re-vaccination. How did it fare with these? Of the thirty-four, one who had been re-vaccinated ten years before had a mild attack. The other thirty-three escaped. Of the six, "the only one ..... who escaped attack was the matron, who visited the wards occasionally but took no part in the actual nursing of the cases."[2] The other five took small-pox, and one of them died. What better control experiment could be thought of than this?

In connexion with these cases of small-pox among nurses, however, a curious light is thrown on Mr. Biggs's mental attitude towards vaccination. Reverting to his criticism of our Commissioner's statement as to the vaccinal condition of the officials we call attention to the following: "Four of these not having been vaccinated since infancy and one not for nineteen years, the term of their 'protection' has theoretically expired." Coming now to the hospital staff in the 1892-93 outbreak and to the six who "although they had not previously been re vaccinated refused to submit to the operation"[3] we find, as already mentioned, that five of the six were attacked and one died. One of the five had ultimately consented to the operation, "but it was only performed on the day that she showed premonitory symptoms of small-pox" We know not whether the six in 1892-93 included the five spoken of by Mr. Biggs in the above quoted passage referring to 1886 but it matters not, as they belonged to the same class as to whom Mr. Biggs insisted that "the term of their protection had theoretically expired." Will it be believed that when five of the six in 1892-3 had been attacked by small-pox, Mr. Biggs wrote thus regarding them to the London *Star?* "During the present outbreak, which began in September last, five of the nurses and attendants at the hospital, all well vaccinated (one of the nurses being re-vaccinated), have been attacked with small-pox. One of these, a very bad case, died of confluent small-pox." The letter in which Mr. Biggs asserted that after nineteen years protection had theoretically expired was printed in the *Times* of Oct. 15th, 1887, and the letter in which he described the cases of 1892-93 as well vaccinated and one of them as re-vaccinated, is to be found in the *Star* of March 1st, 1893.

In order that our readers may have before them the full facts regarding these nurses we turn to Dr. Coupland's Report, p. 33. The ages of the five were forty three, forty-five, twenty-five, twenty, and twenty-three years. All had been vaccinated in infancy. The three younger patients had mild attacks. The two older had severe attacks, and one of them who had been intemperate died. It was one of the younger patients who was re-vaccinated during the premonitory symptoms of the attack, and who was described in Mr. Biggs's letter to the *Star* simply as "re-vaccinated." The others, in spite of their protection having "theoretically expired," he described as "well vaccinated."

In the same line of things it may be noted in passing that to a conference of anti-vaccinationists held in February, 1893, Mr. Biggs declared that the tramp with whom the Leicester outbreak began "was well vaccinated." Dr. Coupland's description (p. 26) is that he had "a smooth, small cicatrix on the arm where he said that he had been vaccinated in infancy." He was thirty-five years old—far more than "nineteen years" from infancy—and there was no evidence that he had ever been well vaccinated.

(To be continued.)

[3] Royal Commission's Final Report, p. 82.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD, 1895-96.

THE supplement of the medical officer to the twenty fifth annual report of the Local Government Board is, as its predecessors have been, full of interest not only to the medical profession but to all who concern themselves with the progress made in our knowledge of the means of combating disease. The student of the volumes which are annually issued by the medical department cannot fail to be impressed with the great strides which this knowledge has made in the quarter of a century which has passed, and of the immense gain it has been to this country to have so much reliable scientific knowledge made available by the medical department for the guidance of the administrations of the Local Government Board and of the sanitary authorities which act under its supervision. The immensity of the work which the medical department has done during the year cannot be appreciated by any reader of the volume under notice who is not himself familiar with the amount of labour which each item referred to involves. Thus the long lists of local inquiries held in connexion with proposals of local authorities as to hospital provision, as to whether orders should be issued in respect of the removal of excrement and refuse removal, as to the incidence of disease in particular places and to their sanitary administration, as to the sanitary condition and administration of a number of districts, and as to river pollution and water-supplies, have only passing notice. Sir Richard Thorne gives account in the main only of inquiries from which some lesson of general application can be learned, but of these there are many which bear ample evidence of the ability with which the work of the department is directed and of the value of its investigations.

In the matter of vaccination Sir Richard Thorne has to record that the marked and almost continuous increase in the amount of default which has been in progress during the last seven years received in London a slight check in respect of 1893, but in the provinces it underwent still further augmentation. This regrettable circumstance is no doubt due to the delay in the presentation of the report of the Royal Commission on Vaccination, boards of guardians in numerous instances regarding the appointment of this Commission as sufficient reason for suspending the operation of the vaccination law. Indeed, the report of this Commission itself contains evidence of this neglect of many of the boards, and as a result some 16·4 per cent. of the children born in England and Wales in 1893 are left susceptible to small-pox It is deserving of note that the number of children returned as insusceptible to vaccination has now reached so high a figure as to represent in England and Wales more than one child in every 300 born, and in London more than one child in every 200 born. The explanation of this extraordinary result is not obvious, but the subject deserves the serious attention of the profession Sir Richard Thorne has abundant material before him to show that "true insusceptibility to vaccination is very rare," for the Local Government Board's own vaccinators, who during the last fifteen years have performed no less than 95 677 primary vaccinations, have not met with a single case of insusceptibility; and further, Sir Richard Thorne points out

Digitized by Google

that the experiences of these officers does not stand alone, "the same result has followed on the vaccination of many thousands of infants in the hands of other public vaccinators." A record, therefore, of 3394 cases of insusceptibility to vaccination in 1893 cannot fail to engage the attention of Parliament in the next session, when it may be presumed the subject of vaccination will be under discussion.

Of the investigations of the cause of disease prevalence, of which the report gives account, perhaps the most interesting is that conducted by Dr. Buchanan into an outbreak of enteric fever in the village of Wycombe Marsh. High Wycombe had been found by Dr. Wheaton to abound with the conditions which foster enteric fever and with the result that might be expected, but the interest of the etiologist centres less in High Wycombe itself than in the opportunity which the sewage farm was found by Dr. Buchanan to give for the production of enteric fever in Wycombe Marsh. The inquiry was in no sense an easy one, and, indeed, unless undertaken by an officer having in high degree the ability to solve a complex problem, the actual circumstances in which the inhabitants of Wycombe Marsh suffered from the High Wycombe sewage-farm would not have been appreciated. The sewage of High Wycombe is chemically treated, and the sludge is pumped on to the land to dry, the more liquid sewage being made to flow on to the sewage-farm, whence, after percolation through the soil, it passes by deep pipes into the back river, a tributary of the River Wye. This back river passes through the farm and is dammed at a mill lower down. This damming of the back river led it to overflow its banks and flood a meadow, which had thus been under water during some weeks at the end of 1895. Subsequently to September of that year cases of enteric fever occurred in Wycombe Marsh, the houses of which are supplied with water from wells in their gardens. Leaky cesspools exposed some of these wells to pollution, but the distribution of the cases of disease did not coincide with that which might have been expected if this had been the cause of enteric fever, indeed no hypothesis met the required conditions other than that the subsoil water supplying the wells had been polluted by the soakage of the back river water through the meadow which it flooded. That there was intimate relation between the back river and some of these wells was shown by the fact that the water in these wells rose when the water in the back river was high. But the circumstance that made the connexion between the flooding of the meadow and the pollution of the Wycombe Marsh wells a practical certainty was the coincidence in point of time between the occurrence of the cases of enteric fever and the damming of the back river. Before September the mill had been disused and hence the water flowed readily away, but in September the mill again came into operation, the river was dammed, and the results described followed. Sir Richard Thorne points to the fact that especial interest attaches to this outbreak because it illustrates a danger which may devolve on one community as the result of works carried out solely in the interests of another community. Dr. Buchanan's inquiry leads the reader of his report to speculate upon the question whether other sewage schemes have been adopted which may in their turn be similar causes of danger. The circumstances of the Wycombe Marsh outbreak undoubtedly suggest the need for careful examination of sewage works which have not hitherto been thought of as possible sources of risk. In his observations on the prevalence of enteric fever in High Wycombe Sir Richard Thorne observes that "accurate knowledge as to the extent of any prevailing preventable disease was so far a matter of indifference to the town council who constitute the sanitary authority of the district that they had not cared to adopt the Act for the Compulsory Notification of Infectious Diseases." The censure implied in these words is well deserved, but we may not unreasonably ask if there is so strong a moral obligation upon a sanitary authority to require notification, whether the time has not arrived when Parliament should impose a Statutory obligation on all such bodies. The very large extent to which this Act has been adopted, the fact that the system of notification was imposed upon London without question and without a murmur from its inhabitants, appears to us to indicate that the time has fully arrived when Parliament might and should take this step.

Sir Richard Thorne includes in his volume two reports illustrating the spread of diphtheria by elementary schools. The first of these, by Dr. Sweeting, relates to a severe outbreak of the disease at Llanfynydd, in Carmarthenshire. This village is evidently an example of sanitary neglect. Dampness of houses, water-supplies exposed to constant risk of pollution, privy accommodation wanting and when existing serving to pollute soil, air, and water; such is the record of Llanfynydd. The beginnings of diphtheria remind the reader of this report of Sir Richard Thorne's early observations as to the manner in which this disease increases in intensity. Undefined throat illness first occurred among the children attending the national school, until at last well-defined diphtheria was recognised, with the result that the school was closed; but the mischief which the villagers suffered had not come to an end when fifty-two persons had been attacked and seventeen had lost their lives. Here, again, the absence of any requirement as to notification of infectious diseases tended to keep the sanitary authority in ignorance of the need for their intervention. The story of this village, Sir Richard Thorne says, is by no means an uncommon one in the experience of the department. "It is one of persistent sanitary neglect, in which preventable disease, getting a foothold on the population before it is recognised, finds everything at hand to favour its fatal diffusion." The second outbreak of diphtheria, investigated by Dr. Reece, occurred in the borough of Flint. Between February and mid-July, 1894, fourteen cases of diphtheria were notified in a population of 5000. Then there was a lull for some two months, followed by a steady increase in the number of cases. At this time the disease had obtained a footing in the schools, and Sir Richard Thorne tells us that at the time of Dr. Reece's visit, 288 children were in actual attendance at one of the five elementary schools in the district of which no less than 113 admitted that they had suffered from "sore-throat" or glandular swellings styled "mumps" during the previous five months, 84 of whom had been absent from school by reason of these ailments, "but no system of exclusion or school closure had been adopted by the town council, and this notwithstanding the fact that at one stage of the outbreak the medical officer of health advocated the closure of the schools." Several cases of inflamed throats were, indeed, on the same occasion, found amongst scholars and teachers. "Under circumstances such as these," says Dr. Reece, "it can scarcely be wondered at that school attendance has been the means of spreading diphtheria in Flint."

(To be continued.)

THE INDIAN FRONTIER.

As we, in common with most people, supposed would be the case, the opposition of the frontier tribes has assumed the character of a harassing guerilla warfare. Night attacks on camps and attacks on convoys and small or detached bodies of troops, on foraging parties, or on the rear of brigades have been, and are likely to continue to be, of frequent occurrence. The native tribes, with their intimate knowledge of the country and with every mountain pass, defile, and, in short, with every nook and corner in it, are at a great tactical advantage in this respect; it is quite easy for them to conceal themselves and attack our troops and convoys at various points most advantageous to themselves, and the so-called "sniping," besides its disturbing effect on the occupants of camps, causes in the aggregate much loss of life and many wounded. The late massacre of an officer and men of the Kapurthala Sikhs is much to be deplored. The circumstances attending this occurrence, with the blazing grass and jungle on one side and the foe on the other, and the Kapurthala Sikhs at bay fighting for their lives, make up a stirring and tragic picture of Eastern warfare. The Sikhs and Goorkhas are the best of soldiers, and it is much to be regretted that the source from which they are supplied is far from being an unlimited one. The weather is much colder—especially the nights and early mornings—but the force, generally speaking, enjoys excellent health The sick and wounded are doing well, the hospital service is full of work, and all concerned are full of zeal and energy.

The latest news from India is, on the whole, of a more satisfactory character. The Orakzais have ascertained the terms of submission required and it is believed that

Digitized by Google

recognising the futility of further opposition they will accede to them, in which case the Afridi tribes may probably come in and make their submission. From a purely military point of view the campaign has so far been successful, but the occupation of Tirah will be attended with great difficulties. The Bara Valley, fertile as it is, cannot furnish the food and forage supplies required by such a large force and foraging parties sent out to collect these usually have to confront attacks from the tribes who have adopted the policy of guerilla tactics. Moreover, the cold will soon become severe with probably ice and falls of snow. Additional accommodation for housing the troops will then be required and the transport of stores and commissariat supplies to the front will become more and more difficult, and diseases of the respiratory organs among the native troops may be expected to prevail. The future policy to be adopted will be greatly influenced, no doubt, by these considerations and by the events that are now taking place. India most probably cannot support the cost of the large force that will be required for the occupation of the conquered country and it is not likely that the Afridis will become reconciled to our presence there—at any rate not for a long time. If they come in, proffer their submission, and sue for terms, it seems probable that, having already read them a severe lesson, the "politicals" will not lose the opportunity of settling the matter on the best practicable terms they can. The expeditionary force will in that case march through the country and retire from it rather than incur the present and future expense of remaining. According to the latest telegraphic intelligence General Kempster's brigade has captured at Mullah Akbar's fort compromising correspondence which is alleged to implicate certain Afghan officials. The situation as it stands at present has many grave political considerations to be taken into account.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Nov. 11th, the President, Sir WILLIAM MACCORMAC, Bart., being in the chair.

The Museum Committee, in their report, recommended that in future the Museum should be open from 10 o'clock to 6 o'clock between March 1st and August 31st, and during October, and from 10 o'clock to 4 o'clock between Nov. 1st and the last day of February. The recommendation was adopted.

Felstead School and Watford Endowed Schools were added to the list of recognised places of instruction in Chemistry, Physics, and Practical Chemistry; and the South-West Polytechnic Institute, which was already recognised for instruction in these subjects, was added to the recognised places of instruction in Elementary Biology.

The PRESIDENT stated that the Bradshaw Lecture would be delivered by Mr. Alfred Willett on Wednesday, Dec. 8th, at 5 P.M., and that the subject of the lecture would be the Correction of Certain Deformities by Operative Measures upon Bones.

The SECRETARY reported that notices of resolutions for the meeting of Fellows and Members on Nov. 18th had been sent in. (These have already been reported in THE LANCET of Nov. 13th, p. 1262.)

A letter was read from the Registrar of the Mason Science College, Birmingham, requesting the Council to appoint a governor in accordance with the provisions of the Mason University College Act, 1897. Sir William MacCormac was appointed for five years.

The Council, after discussion, decided to defer the further consideration of the letter from the Parliamentary Bills Committee of the British Medical Association asking the Council to join a deputation to the Secretary of State for War on the subject of the Army Medical Service.

Mr. MACNAMARA moved, and Dr. WARD COUSINS seconded, the following resolution: "That the President of the Royal College of Surgeons of England be empowered to arrange with the President of the Royal College of Physicians of London to approach the Secretary of State for War to impress upon him the necessity which exists for granting medical officers of the British army substantive army rank and military titles in a consolidated army corps."

The resolution was carried.

THE POLLUTION OF WATER-SUPPLIES BY ENCAMPMENTS OF HOP-PICKERS, CASUAL WORKERS, TRAMPS, ETC.

SIR DOUGLAS GALTON, F.R.S., presided over a well-attended meeting of the Sanitary Institute at the Parkes Museum on Wednesday last, Nov. 17th, when Professor W. H. Corfield opened a discussion in reference to the Dangers of Pollution of Municipal Water-supplies and Miss Chreiman read a paper in reference to the Sanitary Control of Hop-pickers.

Professor W. H. CORFIELD, after referring to some lines of Virgil to show that the danger of polluted water was recognised even in Vigil's time, said there was no doubt whatever that diarrhœa could be communicated by means of polluted drinking-water, but he did not know nor was he aware that anybody knew of any serious outbreak which could be attributed to that cause. He felt strongly that summer diarrhœa in many instances was closely connected with this cause. Serious outbreaks of scarlet fever and diphtheria were not traceable to drinking-water either on a large or small scale. Diphtheria might be communicated by a deliberately contaminated water-supply. Cholera could be distinctly shown to be communicated by contaminated water-supplies. Professor Corfield then quoted a case which had come under his own observation which showed that a person might have enteric fever and go about his work until the third week and then die almost immediately. People might thus spread the poison unknowingly. In the old days of Millbank Prison it was undoubtedly a hotbed of typhoid fever. There were constant cases of abdominal disorders; but when the authorities ceased to use the water which they baled out of the Thames and obtained a supply from the artesian wells which serve the Trafalgar-square fountains these diseases at once disappeared. It was generally assumed that enteric fever and cholera poisons were distributed in the same way; but while it was true that both were conveyed by water there was a difference between the two which was not yet understood. Lyons, for example, was a hotbed of typhoid fever, but had never had a case of cholera; the outbreaks that had occurred outside had never spread into that city. So well was this known that during cholera epidemics people went to Lyons, knowing it would not spread there. Professor Corfield concluded by reading the following letter, which he had received from a medical gentleman in Kent: "The hop-growing extends from a little west of this place (Hildenborough) eastwards to beyond Maidstone, and during the season of hop-picking the country is covered with encampments of people of the least sanitary class, frequenting by preference the proximity of streams and rivers for the convenience of obtaining water and of washing their clothes. It is a confirmed belief amongst this class of people that the hop fields are very health-restoring to the feeble, the sick, and the convalescent, and no doubt that many a convalescent from typhoid is taken to the hop fields, and their linen, which may not have seen the tub for weeks, is washed in the adjacent stream. Should any of the streams become polluted during the present outbreak at Maidstone by cases removed from that town during convalescence it might spread the disease into the villages and amongst the rural population. I have not seen this state of things alluded to in any of the correspondence in the medical or lay press and I think that it is not known what a large number of people are dependent for their water for daily use on the streams and rivers of this county."

Miss M. A. CHREIMAN in her paper described the condition of the hop-pickers and their surroundings which had come under her notice. She described the state of things as being most unsanitary and pleaded for increased sanitary control by the local authorities and better provision for the hop-pickers by their employers. Referring to a reservoir at Farleigh she said she had been told that it had not been cleaned out for eighteen years and when it was being cleaned dead babies were found in it.

Mr. G. H. FOSBROKE (Worcester) spoke of the utility of Section 314 of the Public Health Act, 1875, which gave local authorities the power to make by-laws, but said that it failed in some cases because it left the matter optional. The word

Digitized by Google

"may" in the clause ought to be changed to "shall." The many outbreaks of scarlet fever and diphtheria which occurred in his district after the hop-picking season was over would lead him to believe that disease was imported by these casual workers.

Dr. TEW (Tonbridge), Mr. ADAMS (Maidstone), Dr. THRESH, Dr. PORTER (Stockport), the Rev. EMBLETON THOMAS, and Major L. FLOWER took part in the discussion.

THE PLAGUE IN INDIA.

ALTOGETHER apart from the frontier war the Government of India and the authorities of the India Office at home are confronted with a very grave and anxious duty in having to deal with the plague the spread and progress of which in India is a really serious matter. As was confidently expected there has been a recrudescence of bubonic plague in Western India with the advent of the cold weather, and the disease has, moreover, manifested itself in other and distant provinces and districts, cases having occurred in the Madras Presidency, in the North-West Provinces, in the Punjab, and in Central India and Rajputana. At Poona and in the towns and villages thereabout there has been an alarming increase in the number of cases during the past month; the number of patients admitted to hospital and under treatment is double what it was and the mortality is very large. According to the latest telegram (Nov. 15th) the epidemic in the city and cantonments shows no abatement. There were 630 plague patients in the Poona hospitals, and there had been 134 cases and 94 deaths during the preceding forty-eight hours. The city is completely deserted and several of the principal streets are closed. At Sholapore, Nasik, and other towns and villages there have been numerous attacks. Nasik is not very far from Deolalie, the military depôt through which our troops have to pass in their railway journey on arriving at, and leaving, India.

It will be remembered that an outbreak of plague occurred some time ago at Hurdwar, but owing to the prompt and energetic action of the local authorities the disease did not spread. Still, it is believed that it was carried into the Jullundur district of the Punjab where some cases of plague have recently occurred. The Punjab Government have taken stringent measures in regard to this outbreak. The *Standard* of the 15th inst. contains an interesting communication from its own correspondent on the plague in India and the spread of the infection in which it is stated among other things that at Hurdwar the disease was communicated to the monkeys which always congregate in large numbers on such occasions. The Government of India and the local governments are, it is needless to say, using all vigilance in their efforts to limit the spread of the disease.

Lord Sandhurst, the Governor of Bombay, visited Poona on the 29th ult., inspected the plague hospitals and camp, and expressed himself satisfied at the way in which everything was being conducted. Lord Sandhurst also visited Sholapore on Oct. 21st and inspected the hospitals and segregation sheds at that station. The exodus of people from these places has, as might be expected, been very great and much inconvenience has resulted from the want of native labour. Surgeon-General Cleghorn, C.S.I., was expected at Bombay with the view of making special inquiries into the plague.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6324 births and 4009 deaths were registered during the week ending Nov. 13th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 16·9 to 18·1 per 1000, further rose last week to 19·0. In London the rate was 19·4 per 1000, while it averaged 18·8 in the thirty-two provincial towns. The lowest death-rates in these towns were 10·7 in Cardiff, 11·7 in Plymouth, 13·3 in West Ham, and 13·9 in Gateshead; the highest rates were 23·1 in Liverpool, 24·7 in Sheffield, 25·4 in Preston, and 26·5 in Burnley. The 4009 deaths in these towns included 461 which were referred to the principal zymotic diseases, against 463 and 412 in the two preceding weeks; of these, 157 resulted from measles, 70 from diphtheria, 68 from diarrhœa 61 from whooping-cough, 59 from "fever" (principally enteric), and 46 from scarlet fever. No fatal case of any of these diseases was recorded last week in Birkenhead; in the other towns they caused the lowest death-rates in Brighton, Newcastle-upon-Tyne, Portsmouth, and Hull, and the highest rates in Bolton, Bristol, Gateshead, and Blackburn. The greatest mortality from measles occurred in Huddersfield, Sunderland, Gateshead, Swansea, Croydon, Oldham and Blackburn; from scarlet fever in Gateshead; from "fever" in Bristol; and from diarrhœa in Wolverhampton and in Bolton. The mortality from whooping-cough showed no marked excess in any of the large towns. The 70 deaths from diphtheria included 46 in London, 5 in Birmingham, 4 Liverpool, 3 in Cardiff, and 3 in Leicester. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospitals at the end of the week was 3777, against 3685, 3682, and 3680 on the three preceding Saturdays; 460 new cases were admitted during the week, against 342, 416, and 339 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 326 and 363 in the two preceding weeks, further rose to 420 last week, and were 14 above the corrected average. The causes of 50, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in Swansea, Leicester, Liverpool, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 20·3 to 18 8 per 1000, rose again to 20·1 during the week ending Nov. 13th, and exceeded by 1·1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·1 in Paisley and 16·6 in Aberdeen to 21·4 in Glasgow and 23·7 in Greenock. The 599 deaths in these towns included 23 which were referred to diarrhœa, 12 to whooping-cough, 11 to scarlet fever, 7 to measles, 6 to diphtheria, 4 to "fever," and 1 to small-pox. In all, 64 deaths resulted from these principal zymotic diseases, against 79 and 70 in the two preceding weeks. These 64 deaths were equal to an annual rate of 2·1 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 15 and 16 in the two preceding weeks, declined to 12 last week, and included 8 in Glasgow and 3 in Greenock. The deaths referred to scarlet fever, which had increased from 4 to 18 in the three preceding weeks, fell to 11 last week, of which 6 occurred in Glasgow and 4 in Dundee. The 7 fatal cases of measles also showed a decline from those recorded in recent weeks, and included 5 in Greenock. The deaths from diphtheria, which had been 3 and 5 in the two preceding weeks, further rose to 6 last week, of which 2 occurred in Glasgow and 2 in Edinburgh. The 4 fatal cases of "fever" included 2 in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 137 and 142 in the two preceding weeks, further rose to 161 last week, but were slightly below the number in the corresponding period of last year. The causes of 35, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·2 and 21·5 per 1000 in the two preceding weeks, further declined to 19·8 during the week ending Nov. 13th. During the past six weeks of the current quarter the death-rate in the city has averaged 22·8 per 1000, the rate during the same period being 17·3 in London and 18·7 in Edinburgh. The 133 deaths registered in Dublin during the week under notice showed a decline of 11 from the number in the preceding week, and included 24 which were referred to the principal

Digitized by Google

zymotic diseases, against 8 and 12 in the two preceding weeks; of these, 10 resulted from "fever" (principally enteric), 8 from scarlet fever, 3 from diarrhœa, 2 from diphtheria, and 1 from scarlet fever. These 24 deaths were equal to an annual rate of 3·6 per 1000, the zymotic death-rate during the same period being 2·5 in London and 1·4 in Edinburgh. The deaths referred to different forms of "fever," which had been 6, 0, and 8 in the three preceding weeks, rose to 10 last week, a higher number than in any week during the past four years. The fatal cases of scarlet fever, which had been 2 and 0 in the two preceding weeks, rose to 8 last week, and exceeded the number recorded in any week during the current year. The 133 deaths registered in Dublin last week included 17 of infants under one year of age and 38 of persons aged upwards of sixty years; the deaths of infants showed a further decline, while those of elderly persons exceeded the numbers recorded in the preceding week. No deaths from violence, and only 1 inquest case were registered; and 50, or more than a third, of the deaths occurred in public institutions. The causes of 7, or more than 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR MULVANY has embarked for Bombay. Surgeon-Captain Robinson proceeds to the Cork District for duty. Surgeon-Major A. F. Russell is posted to Fort George as Medical Officer in Charge of the Station Hospital.

Supernumerary Surgeon-Colonel Robert C. Eaton to be Surgeon-Colonel, vice C. A. Atkins, retired.

Her Majesty the Queen has been graciously pleased to confer the Jubilee Commemoration Medal on Surgeon-Major-General A. F. Preston, M.B. Dub., Principal Medical Officer in Ireland.

Her Majesty has also been graciously pleased to confer the Jubilee Commemoration Medal on Surgeon-Major-General Thomas Maunsell, A.M.S., Principal Medical Officer, Malta.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the under-mentioned officers (Bengal) are replaced temporarily at the disposal of the Military Department:—Surgeon-Major Cunningham, Surgeon-Lieutenant Milne, and Surgeon-Captain Smith. The undermentioned officers to be Magistrates of the Second Class in the District of Satara:—Surgeon-Captain Smith, medical officer in charge of Plague Flying Column No. 2, Karad, and Surgeon-Lieutenant Robertson, on plague duty, Karad villages. Surgeon-Major T. H. Sweeney, Civil Surgeon, Benares, is appointed to officiate as Superintendent, Central Prison, Benares. Surgeon-Captain L. G. Fischer is appointed to the civil medical charge of the Almora district. Surgeon-Major Tuohy, Civil Surgeon, Agra, is appointed to the visiting medical charge of the Etawah district. Surgeon-Major Smith, Civil Surgeon, Shahjahanpur, is appointed to the visiting medical charge of the Hardoi district. Surgeon-Major Hawkins, Civil Surgeon, Moradabad, is appointed to the visiting medical charge of the Budaun and Bijnor districts.

Brigade-Surgeon-Lieutenant-Colonel Caldecott vacates his appointment in Central India on promotion to the administrative grade in the Indian Medical Service, Surgeon-Lieutenant-Colonel Dane succeeds him as civil administrative medical officer in the Central India Agency, and has his headquarters at Bhopal, Surgeon-Major Gimlette, of Rewah, going to Indore as Residency Surgeon.

MILITIA MEDICAL STAFF CORPS.

Surgeon-Lieutenant Stuart Oliver, from the London Companies Volunteer Medical Staff Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Major J. Knox to be Surgeon-Lieutenant-Colonel; Surgeon-Captain W. S. Symes to be Surgeon-Major. 1st Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Captain W. Sneddon, M.D., to be Surgeon-Major. 4th (Stirlingshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): James Hay Murray, M.B., to be Surgeon-Lieutenant.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Surgeon-Captain H. W. G. Macleod, M.D., resigns his commission.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The following officers who have been under instruction from the staff of the school have recently passed the proficiency examination conducted by the Army Medical Staff, thereby earning the higher grant for their corps and becoming entitled to promotion after completing the necessary period of service:—*Colonial Forces:* Brigade-Surgeon-Lieutenant-Colonel H. A. de Lautour, V.D., New Zealand Defence Forces; and Surgeon-Captain F. A. Foy, M.B., 1st Bombay Rifles. *Volunteers:* Surgeon-Major R. Grant, M.A., M.D., 2nd Volunteer Battalion the Black Watch; Surgeon-Captain T. C. Bailey, 2nd Cheshire Royal Engineer Volunteers; Surgeon-Captain F. C. Rogers, 4th Volunteer Battalion Cheshire Regiment; Surgeon-Lieutenant M. A. Cooke, 2nd Volunteer Battalion Gloucester Regiment; Surgeon-Lieutenant J. Robinson, 1st Volunteer Battalion Worcester Regiment; Surgeon-Lieutenant M. Richards, North London Volunteer Brigade Bearer Company; Surgeon-Lieutenant W. H. Forsbrooke, M.D., 1st Volunteer Battalion Royal Fusiliers; Surgeon-Lieutenant H. Allport, 1st City of London Volunteer Artillery; Surgeon-Lieutenant R. A. Johnston, 1st Volunteer Battalion Derbyshire Regiment; Surgeon-Lieutenant C. Rigby, 1st Volunteer Battalion the Loyal North Lancashire Regiment; Surgeon-Lieutenant J. W. Jessop, 1st Volunteer Battalion Lincolnshire Regiment; Surgeon-Lieutenant A. Whitton, M.B., 6th Volunteer Battalion the Gordon Highlanders; Surgeon-Lieutenant R. B. Sidebottom, 4th Volunteer Battalion Cheshire Regiment; Surgeon-Lieutenant F. H. Thompson, 1st Volunteer Battalion Shropshire Light Infantry; Surgeon-Lieutenant T. A. Sellar, M.D., 6th Volunteer Battalion the Gordon Highlanders; Surgeon-Lieutenant J. Kyffin, 1st Hants Royal Engineer Volunteers; Surgeon-Lieutenant F. A. Brooks, M.D., 1st Essex Volunteer Artillery; Surgeon-Lieutenant T. C. Ticehurst, 3rd D.C.O. Volunteer Battalion Hampshire Regiment; Surgeon-Lieutenant A. H. Vernon, F.R.C.S., 4th Volunteer Battalion Hampshire Regiment; Surgeon-Lieutenant V. J. Blake, M.B., 5th Volunteer Battalion Hampshire Regiment; Surgeon-Lieutenant D. Smart, M.B., 2nd Volunteer Battalion The King's Liverpool Regiment; Surgeon-Lieutenant H. Dickie, M.D., 1st Volunteer Battalion Northumberland Fusiliers; Surgeon-Lieutenant H. Legh de Legh, 1st Volunteer Battalion Prince of Wales's Own Yorkshire Regiment; Surgeon-Lieutenant W. P. Peake, 1st Volunteer Battalion Leicestershire Regiment.

Surgeon-Captain R. R. Sleman, "Artists" Rifle Volunteers, has obtained a certificate of proficiency with special mention at an examination conducted by a Board of Army Medical Officers at Aldershot.

TROOPSHIPS AND HIRED TRANSPORTS.

Last May Mr. Labouchere alluded in *Truth* to the overcrowding of the hired transport *Britannia*, stating that she had arrived in England carrying about 1200 persons, whereas according to the Board of Trade certificate she had only accommodation for 692; and recently a correspondent of the *Daily Mail* instanced the case of the *Dunera*, which sailed for India with 1395 officers, men, women, and children on board in addition to the ship's company, in spite of the fact that if she were engaged in private trade her certificate would not permit her to carry more than about 680 passengers. No doubt when a private vessel is taken up for the conveyance of troops the alterations effected in her internal arrangements enable her to carry a larger number of soldiers, who do not require separate cabins, than would be possible under Board of Trade rules, but it is, nevertheless, difficult to understand how her carrying capacity could be more than doubled without entailing overcrowding. According to a note which we published last week[1] Dr. Bonnafy, of the French colonial service, found that for a period of ten years the proportion of deaths among invalids on board Government troopships and hired transports during the voyage from Saigon to Toulon, was eighteen and twenty-six respectively per thousand embarked, and yet there was no more overcrowding in one class of vessel than in the other, and the conditions of life in both were as nearly as possible alike. It would be interesting if similar

[1] THE LANCET, Nov. 13th, 1897, p. 1276.

Digitized by Google

statistics could be published regarding our own transports. The Indian troopers may have been expensive, but if it should turn out that their employment conduced to the saving of life, then most certainly their re-establishment cannot be undertaken too soon. Overcrowding at sea is one of the most fertile sources of disease and death, and should that alleged to have occurred on board the *Britannia* and *Dunera* be a fact it is impossible to believe that no harm resulted therefrom.

THE LATE SURGEON-GENERAL RICHARD GILBORNE.

A correspondent writes to the *Army and Navy Gazette*:—"The intelligence of Surgeon-General Richard Gilborne's death has been received with wide feelings of regret. He was held in high esteem by those with whom he was associated, both officially and socially. He was noted for urbanity and a quiet unassuming mien. Never has an unkind word been said of Dickie Gilborne, nor indeed did any person ever hear "Dickie" say an unkind word of anyone. A large part of the deceased officer's service was passed as a regimental surgeon in the Carabiniers; while in the administrative ranks of the Army Medical Staff he was Principal Medical Officer at Aldershot, Bombay, Colchester, and Hong-Kong. He was a justice of the peace of Folkestone, where he resided since his retirement and there became popular owing to his excellent qualities."

Her Majesty has conferred the Jubilee Commemoration Medal on Surgeon-Captain Charles Pye Oliver, M.D., Commanding the Maidstone Company, Volunteer Medical Staff Corps, in recognition of the services of the Company on Jubilee Day, when about ninety men were on duty near the Horse Guards and rendered first aid in an efficient manner to 150 cases.

Surgeon-Major A. M. Davies has been attached to the office of the Principal Medical Officer with Her Majesty's Forces in India for one year for the purpose of carrying out bacteriological and sanitary investigations in cantonments.

Brigade-Surgeon-Lieutenant-Colonel K. McLeod, M.D., retired, I.M.S., has been granted the temporary rank of Surgeon-Colonel whilst acting as a Professor at the Army Medical School, Netley.

Correspondence.

"Audi alteram partem."

PROPOSED AMENDMENTS OF THE NOTIFICATION ACT.

To the Editors of THE LANCET.

SIRS,—As this question appears to be arousing some attention owing to the action of Dr. Meredith Young and the Crewe town council, I beg to offer you the following further information. In March last I prepared a circular (of which a copy is appended) for the Bucklow rural district council, and it was issued as a *ballon d'essai* to 4 municipal boroughs, 31 urban districts, and 12 rural districts in Cheshire. Out of 47 authorities 26 made no reply whatever, 3 were neutral, and 18 were in favour of attempting to procure an Amending Act. These latter are the municipal boroughs of Crewe and Stalybridge, the urban districts of Alderley Edge, Biddulph, Hoole, Knutsford, Middlewich, Northwich, Runcorn, Sale, Tarporley, Wilmslow, and Winsford, and the rural districts of Bucklow, Congleton, Macclesfield, Northwich, and Runcorn. Here the matter rested until Crewe took the lead and petitioned the Local Government Board. The Bucklow rural district council has now sent up a letter in support of the Crewe petition (in principle, but not binding itself to every detail); and has written to the other authorities named asking them to do the same.

If you, Sirs, would support this suggestion, no doubt medical officers of health all over the country could induce their councils to communicate briefly to the Local Government Board their desire to have an Amending Act. It is now universally admitted, and therefore needs no argument, that the existing Act is very defective. I suggest that details can be left for discussion till the Bill is drafted. What is really wanted first is that the Government shall recognise the justice of our demand and shall prepare a Bill.

I note that Dr. Woodforde made this question the subject of his inaugural address to the Home Counties Branch of the Incorporated Society of Medical Officers of Health, and is in very close agreement with my views. We differ on one or two points from Dr. Meredith Young, but this is not the time to discuss differences; rather let us all be united in pressing for the preparation and production of a Government Bill, and then we can air our respective views on matters of detail.

I am, Sirs, your obedient servant,

Knutsford, Cheshire, Nov. 7th, 1897. T. W. H. GABSTANG.

CIRCULAR.

SUGGESTIONS BY THE MEDICAL OFFICER OF HEALTH TO THE BUCKLOW AND NORTHWICH RURAL DISTRICT COUNCILS, ETC., FOR DESIRABLE AMENDMENTS IN THE "INFECTIOUS DISEASE (NOTIFICATION) ACT 1889," ETC.;

To be laid before the Councils for consideration, with a view to securing the coöperation of other Councils in obtaining an Amending act.

1. FAULT.—(Section 3 (I.) (*b*).)—Every medical practitioner called in must send in a certificate.

REMEDY.—One certificate being sufficient for each case, further certificates ought not to be required or received, more particularly where the second attendant is called in as a consultant, or is related to the first attendant as partner, principal, or assistant.

2. FAULT.—(Section 4 (2).)—Fee for every case in private practice half-a-crown.

REMEDY.—Seeing that one notification brings the infected premises to the notice of the medical officer of health, subsequent cases occurring in one house and during one illness might be paid for at a reduced fee.

3. FAULT.—(Section 6.)—Erysipelas included in list of notifiable diseases.

REMEDY.—Erysipelas to be excluded; or retained only in special cases, as (1) after childbirth, (2) after injuries, or (3) where dangerous to life.

4. FAULT.—(Section 3 (I.) (*a*) and (*b*).)—*Dual Notification.* Head of family and medical practitioner both required to notify.

REMEDY.—The duty should rest upon the medical practitioner alone, being extended to the head of the family only in those cases where no medical attendant is called in.

Note.—The head of the family who subsequently calls in a medical attendant should not thereby be relieved from responsibility for the period of illness preceding such action.

5. FAULT.—(Section 3 (I.) (*a*) and (*b*).)—Notification to be made upon "becoming aware" of existence of infectious disease.

Note.—Any unscrupulous person prepared to assert that he had "not been aware" would have an unassailable defence to any prosecution, and could therefore set the Act at defiance in absolute safety.

REMEDY.—The principle already adopted in Section 116 of the "Public Health Act, 1875," viz., that "proof of innocence shall rest with the party charged," must be introduced, in some shape or other. The onus of proving "knowledge" should be removed from the complainant Council, and proof of bonâ fide "ignorance" should instead be required from the defendant.

6. FAULT.—(Section 3 (2).)—Penalty limited to fine of forty shillings.

Note.—Quite insufficient to prevent deliberate concealment of cases where strong private reasons exist for such a course—e.g., laundries, bakeries, dairies, &c., whose trade would be affected by publicity.

REMEDY.—Amount of penalty to be increased, or nature varied, for cases of proved wilful infraction of the Act.

7. Sundry minor suggestions:

(*a*) (Section 2 (*b*).)—The Act is only permissive. It might well now be made universally applicable.

(*b*) The same remark applies to the "Infectious Disease (Prevention) Act, 1890."

(*c*) If (*a*) were carried out Section 5 would become unnecessary.

(*d*) If the fee paid covers and includes all necessary postages, let it be so stated, to avoid possibility of dispute.

8. "The Public Health Act, 1875."—Section 126—*Penalties on exposure*—This requires extending, to cover the cases of infection carried about by "third persons." At present there appears to be no power under any Act to deal with a midwife spreading puerperal fever; or with casual visitors to scarlet fever cases carrying away the seeds of the disease for communication to fresh victims.

RESPONSIBILITY FOR SURGICAL OPERATIONS.

To the Editors of THE LANCET.

SIRS,—THE LANCET of Nov. 6th published an article in which my name is mentioned in referring to a surgeon's responsibility in surgical operations. The case you mention took place in the practice of Dr. Benjamin Anger and not in that of Dr. Theophilus Anger. We are two surgeons bearing the same name at the Hôpital Beaujon, but are not related to each other. It is Benjamin Anger and not Theophilus Anger that you speak of, and I beg of you to correct your mistake in your next number.—I am, Sirs, yours truly,

THEOPHILE ANGER.
Chirurgien de l'hôpital Beaujon.

105 Bd. Haussmann, Paris, Nov. 11th, 1897.

"THE HOSPITALS, THE PROFESSION, AND THE PUBLIC."

To the Editors of THE LANCET.

SIRS,—I have to thank you for publishing in THE LANCET of Nov. 6th the letter I addressed to you giving my views on

Digitized by Google

certain points of hospital management. I notice, however, that in your editorial comment, instead of dealing with these points you reiterate an accusation which you made against me in a leading article in THE LANCET of Oct. 30th, to the effect that I charged the private practitioner with inefficiency. Now, in my letter to you I took no notice of this because it seemed to me such a ridiculous affair. I was concerned for matters touching hospital management, not for mere personal attacks upon myself. But if you intend seriously to maintain the position taken up in your leading article that in matters of hospital reform a man is to be boycotted by the medical profession if he do but venture to suggest that all the error is not on the side of the hospitals, the effect must be, so far as you have any influence with the medical profession, to indefinitely postpone the proper consideration of hospital reform. It is perfectly notorious that people are not attracted to hospitals solely by motives of economy, but go there because they believe that they get something better in the way of treatment than they can obtain from some medical practitioners to whom they would otherwise have to go. Moreover, this feeling has grown up not altogether as a mere sentiment, but sometimes as the result of experience among people who have had plenty of opportunity of trying both kinds of treatment.

Anyone, then, who would deal fully and completely even with that side of the hospital problem which is included in the term "hospital abuse" must recognise both sides of the question. Perhaps the competition of the hospitals may be to some extent responsible for the starving of some classes of medical practice, but whatever the cause it is impossible not to see that in the cheaper practices, which are the alternative open to many who now go to the hospitals, there are sometimes second-rate medical attendance and medical appliances. It is idle to shut one's eyes to the fact that the hospital problem involves a consideration of the existing conditions of practice not only within but outside the hospital doors; and knowing what I do on the subject I have suggested that it is not enough merely to refuse admission to certain out-patients, but that steps should also be taken to ensure that the outside practitioner should have access to the scientific advantages offered by the hospitals as educational centres, and thus should be enabled to give to his patients the same treatment that is current at the time in the most advanced centres of medical knowledge.

I believe that the mass of the very practitioners on whose behalf you write so indignantly will be the first to recognise the advantage of being allowed free access to especially arranged post-graduate courses, recognising, as I know they do, the progressive nature of medical science and the difficulties which exist in keeping abreast of the times amid the turmoil of general practice. I consider that you are not only misrepresenting the sentiments of the medical profession, which are always in favour of progress, but are putting a great obstacle in the way of hospital reform when you say (because I have ventured to put this matter into precise words), "It will become a serious question, if these are really Sir Henry Burdett's views, whether medical men should be asked to appear on the same platform with him again for the promotion of hospital reform." Medical men are not so fond, Sirs, as you would appear from this suggestion to think they are, of being placed in a false position and of being made ridiculous.—I am, Sirs, your obedient servant,

HENRY C. BURDETT.

The Lodge, Porchester-square, W., Nov. 9th, 1897.

*** Sir Henry Burdett repeats himself. He also misrepresents our position. We insert his letter but see no reason therein to cause us to change our previously expressed opinion.—ED. L.

"THE PREHENSILE POWER OF THE HANDS OF THE HUMAN INFANT."

To the Editors of THE LANCET.

SIRS,—I have read Dr. Walter Kidd's letter upon "The Prehensile Power of the Hands of the Human Infant" with a great amount of interest. I agree with his line of argument, and particularly when he remarks that if man had any genetic connexion with the ape the "vestige" of prehension of his foot ought to be a more marked character than the corresponding "vestige" pertaining to his hand. I have read also with interest Dr. Reid's reply in THE LANCET of Oct. 23rd. To oppose Dr. Kidd's theory he introduces embryological lore; he discusses as vestiges (or rather in their relation to vestiges) the branchial arches, an embryological thirteenth rib, and the os centrale. But I fail to understand why the finding of evidence of the os centrale in the human embryo or similar discoveries in connexion with a thirteenth rib or the branchial arches should help to establish any other theory than that of the inter-relation of species. Embryological study shows us a human tail of which we should be much prouder than we should be of our developed coccygeal apparatus, but does this point to a simian ancestry? I think as far as tails are concerned we should be more nearly related to certain varieties of dogs. There is a variety of Yorkshire sheep dogs which is as tailless as is man. Does not embryology really point to a general ground plan rather than to the more generally accepted idea of evolution. Take for another example the attributes of sex: there is the stage of embryonic life when the sexual apparatus cannot be differentiated; we cannot say whether a given embryo would have developed a penis or a clitoris, a scrotum or labia majora, or a uterus masculinus, or a uterus. These appearances surely do not mean that man was evolved from a woman or a woman from a man, or that either or both were ever sexless. Of course it may be said that is not fair analogy, but I will give my reasons for asserting that it is. We know that man will have, and has always had, twelve ribs in spite of the embryological thirteenth rib. We know also that we can often find in the adult man the "rudiments" of the embryological structure, but nevertheless he has twelve ribs only, even when we go as far back as palæontology will permit. Similar repetition of fact and sequence occurs with the sexual attributes.

I am, Sirs, yours faithfully,

Reading, Nov. 14th, 1897. W. T. FREEMAN.

P.S.—The early embryological sexual attributes to which I have drawn attention most probably point to an hermaphroditic ancestry, but such a deduction may also be applied to the rest of the animal and plant world. The evidences of this in plant life are, of course, more apparent than they are in animal life.

THE BRITISH MEDICAL ASSOCIATION AND MEDICAL DEFENCE.

To the Editors of THE LANCET.

SIRS,—It was decided at the annual meeting of the British Medical Association last July that voting cards should be issued to the British and Colonial branches, asking for a simple answer whether we should undertake medical defence or not. In a few weeks these cards will be in our hands, and it is to be earnestly hoped that every member will vote. There is no excuse for anyone not having formed an opinion, or for being too careless to fill in a reply post-card.

It may be of value to recapitulate the argument in favour of the adoption of defence. The invasion of the functions and livelihood of general practitioners by illegal practice and drug-selling increases steadily, and there is no organised body to withstand it, except the present private defence unions. The chartered corporations, in defiance of their charters, refuse to attempt to protect their members, and have resolved themselves into purely examining bodies. Only the expenditure of large sums could force the Colleges to reassume their functions of protection; it would therefore be more practical for the members of the Association (which includes the bulk of the profession) to subscribe for this provision of protection to be administered by their own nominees. As to the necessity for or advisability of collective defence many members are doubtful, but none deny that without the safe-guard of some coöperative union for defence of individuals, practice is quite impossible. The only question is whether the Association or existing private unions can best administer this office. It is obvious that the larger and richer the administrative body is the better for its members. The existing societies need wider membership and larger reserve funds, both of which the existing organisation of the Association can supply. We already need a court of arbitration among our own colleagues to decide questions of libel and professional conduct. Such questions are often incapable of proper solution by ordinary courts of law; they are too frequent already and they will become more frequent as the present competition and pressure increase in the ranks

Digitized by Google

of a profession the members of which are becoming less and less regardful of the etiquette of professional life.

Such a board of arbitration will be afforded by the Association Defence Committee or committees, and it will be a great advantage to have for further reference (if necessary) of doubtful inter-professional cases, the Council of the Association appointed not for defence but for general purposes. We have ready made an organisation which has trained its committees in varied legal and Parliamentary work; we should have no difficulty in training another one, while we know that most of the skilled executives of the principal defence societies will be placed at our disposal if required. The scientific work of the Association will be no more injured by this departure than it has been by the other political work.

I am, Sirs, yours faithfully,

Westerham, Nov. 15th, 1897. A. MAUDE.

THE HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—May I be allowed once more to appeal to the profession for financial help to enable the Hospital Reform Association to carry on its work? Men as a rule have short memories, and I may therefore be pardoned for reminding them that since our establishment in October of last year we have held meetings in London, Liverpool, Birmingham, Manchester, Brighton, and Bristol; that we have communicated with the authorities of every hospital in England and Wales; that we have petitioned the Royal College of Physicians of London; and that we have made an investigation into and published a report on the special hospitals of the metropolis. Whether we have succeeded in arousing public opinion I will leave others to judge. I may, however, be excused for mentioning one or two facts which may or may not have some connexion with the work of propagandism that we have undertaken. In the first place, the authorities of the general hospitals with medical schools have drawn up a series of recommendations for the better administration of the out-patient and casualty departments. In the second place, the Council of the Hospital Sunday Fund has recommended the London hospitals to appoint inquiry officers. And, in the third place, the Duke of Devonshire has spoken of the question of hospital abuse as one that deserves investigation. Considering our youth and the very small number (150) of members who have associated themselves with the work, we may be pardoned for saying that our record is not a bad one.

I am, Sirs, your obedient servant,

Cardiff, Nov. 15th, 1897. T. GARRETT HORDER.

ATHLETES AND LARGE-SIZED HEARTS.

To the Editors of THE LANCET.

SIRS,—I read in the *Sportsman* of to-day that F. E. Bacon in his three-quarters-of-a-mile race on Saturday at Catford Athletic Grounds with E. C. Bredin, "again proved what a remarkable athlete he is, for he finished almost as fresh as when he started." The three-quarters of a mile was raced in 3 min. 22½ sec. I cannot help thinking that it would be worth recording the result of an expert professional examination of F. E. Bacon's heart. I bear in mind that Eclipse, the racehorse, and Master McGrath, the champion greyhound, were found post mortem to have very large hearts, so carrying off the great pressure of the increased circulation during the times of racing. It has been said that neither of these animals required much training for their races. I do not know if this is equally the case with Mr. Bacon.

I am, Sirs, yours faithfully,

Canterbury, Nov. 15th, 1897. PUGIN THORNTON.

THE LATE SIR W. MACKINNON, K.C.B.

To the Editors of THE LANCET.

SIRS,—Although extremely reluctant to appear in print where my own services are concerned I feel constrained to correct some singular inaccuracies in the latter portion of your obituary notice of my distinguished friend Sir William Mackinnon. For instance, at the Gate Pah you state: "The officers were one by one wounded or killed and none remained unhurt but Mackinnon. He took command of the men, rushed the Pah, captured it ....." This is so absurd and ridiculous an assertion that it scarcely needs contradiction; but as I was present on the occasion referred to, and Dr. Mackinnon was serving under my orders, I had better state what actually occurred. At the assault on the Gate Pah owing to the paucity of medical officers available for this duty Dr. Mackinnon and myself accompanied the troops into action, taking up a position in rear of the supports, attended by two orderlies to carry our "field companions." When the attacking party and the supports who rushed in with them were driven out of the Pah we found ourselves and a number of wounded men isolated and absolutely unprotected, a panic having seized the retreating troops. At that moment a body of natives emerged from the Pah and were making direct for us. We never for a moment thought of abandoning our helpless charge and I directed the two men who so manfully stood by us to fire. Dr. Makinnon, hastily snatching a rifle from one of the fugitives, also fired and wounded the leading chief in the heel. This and the fire of the two men caused them to hesitate and pause, evidently suspecting an ambuscade, for we were partially concealed by high ferns. Our perilous position having been perceived by the General a hundred men of the Naval Brigade were hastily dispatched to our assistance, the General himself and his staff speedily following. Sir Duncan Cameron, with the nobleness of character so characteristic of him, addressed some handsome remarks to us, describing our conduct as an example to the troops. The next morning he sent for me to elicit full particulars of the occurrence, and informed me of his intention of recommending us, as well as another medical officer (Dr. Manley) who accompanied the storming party into the Pah, for the Victoria Cross. I pointed out that I already possessed it, and did not feel justified in accepting further distinction merely for doing my duty in not deserting my post. He replied, "But what about Mackinnon—do you think he would be satisfied with the Order of the Bath?" When I mentioned this to Dr. Mackinnon he at once acquiesced. The General wished what took place to be considered confidential, but as he afterwards alluded to it in an official memorandum to the Military Secretary in the following terms I feel justified in quoting it. The incident is thus referred to:—

"Dr. Mouat invariably accompanied the force operating in the field under my command, and I wish to mention an act of conspicuous bravery performed by him at the assault on the Gate Pah, when Dr. Mackinnon and himself remained (after the retreat of the troops), attending the wounded men who had fallen near the entrenchments, exposed all the time to a close fire from the enemy's works, and in so dangerous a position that Dr. Mackinnon at one time was obliged to snatch a rifle and fire to keep back the enemy, mortally wounding a well-known leading chief. For his gallantry on this occasion Dr. Mackinnon was appointed a Companion of the Bath."

The statement regarding operations on the elbow-joint is not quite correct. It was not the elbow-joint, but excisions of the head of the humerus of which he was justly proud, as there were eight successful cases of this class, some of which were performed by him, but others by Sir A. Home and myself.

In conclusion, I wish to bear testimony as an old friend of thirty years' standing to his many excellent qualities both as a friend, a soldier, and a surgeon. With regard to his views on the question of military rank he held the same opinions as myself: that soldiers only understand one kind of rank—that is, military rank expressed by military titles; and if the medical department is in future to be anything more than a mere cypher and a sham in the military hierarchy it will have to come, and the sooner it comes the better.

I am, Sirs, yours faithfully,

J. MOUAT,

Nov. 10th, 1897. Surgeon-General (Retired).

*** The passage in the obituary notice was written by a distinguished surgeon. We are glad to publish Sir James Mouat's interesting account of the stirring episode of the Gate Pah.—ED. L.

THE ATTENDANCE AT HOSPITALS OF THE HONORARY STAFF.

To the Editors of THE LANCET.

SIRS,—The question of an attendance-book to be signed by the honorary medical staff having been under consideration at this hospital I have ascertained the practice in this respect at other metropolitan hospitals and the results of my inquiry appear so interesting that they are submitted to you for publication.

Although but at few institutions the hour of departure is

Digitized by Google

noted, its adoption was recommended to our committee, since the record demonstrates the amount of time which is devoted to the patients by the honorary staff, a point hardly appreciated by the general public. The figures include twenty-one general and fifty-one special hospitals. At seventeen general and at thirty-nine special hospitals an attendance book is employed; at one it was employed but fell into disuse, while at two others the subject is now under discussion; at ten only is there no registration. Two institutions did not reply to my inquiry. At thirty-nine institutions the medical staff are required to register their names and the hour of arrival, at nine both the hour of arrival and departure, and at the remaining eight the registration is carried out by an attendant. All the hospitals for phthisis and diseases of the chest have an attendance-book, and at two of them the staff sign both the time of arrival and departure; at all the ophthalmic hospitals an attendance-book is in force, at one of them the staff signing both in and out. At nine out of the ten hospitals for women—including lying-in—the attendance-book is employed. At six of the nine children's hospitals it is in use, and at one of them the question of its introduction is now being discussed. In two of these hospitals the rules on the subject of signing are very stringent. Of the four hospitals for diseases of the throat and ear the staff sign their names, together with the hour of arrival and departure at three of them, and in one case the arrival only.

I am, Sirs, your obedient servant,

RICHARD KERSHAW,

Secretary, Central London Throat and Ear Hospital.

Gray's Inn-road, Nov. 16th, 1897.

"A TESTIMONIAL TO DR. JOHN T. ARLIDGE."

To the Editors of THE LANCET.

SIRS,—I will feel much obliged if you will insert in THE LANCET the following list of subscribers to the testimonial to Dr. J. T. Arlidge to present date.

I am, Sirs, yours faithfully,

CHAS. F. MOORE.

DR. R. R. RENTOUL'S RESIGNATION OF MEMBERSHIP OF THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—When I resigned my position of Direct Representative upon the Medical Council I promised privately and publicly to give my reasons for so doing. Before doing so let me try to correct a strange idea which seems to possess the minds of some practitioners to the effect that they conferred upon me some marked honour when they voted for my election to the Council. I have never and shall never consider any such election an honour. In 1891 I was asked to stand; my expenses guaranteed, but I refused. In 1896 I publicly stated I would withdraw my candidature if Mr. Wheelhouse and Sir W. Foster agreed to stand again, and in 1897 I resigned as I came to the finding that I could not accomplish any of my work as member of the Council constituted and worked as it now is. Every honest practitioner must recognise that a practitioner—and especially a practitioner in general practice—must do great injury to his practice if he not only leaves it three or four times each year, but what is more, if he gives a very great share of his time to preparing and working up business to bring before Sessions and Committees of the Council. To attend meetings of the Council simply for the "honour" of sitting at the Council's meetings is not to my liking.

My first reason for resigning is that the 6646 practitioners who voted for me practically deserted me immediately afterwards. I think most sane persons will agree that to put a man in a position to fight and carry out a forward policy he must be thoroughly supported morally and financially. As to the want of moral support, I may mention one case only. Early this year, after prolonged work, I drafted a Bill for the Registration of Midwifery and other Nurses. I sent a copy of this to about 129 Medical Societies in the United Kingdom and to about 46 Branches of the British Medical Association, with a request that each should refer this Draft Bill to a committee and ask their M.P.'s to support it and to let me know. Other than practitioners will have difficulty in believing me when I state that only three of these Societies and Branches had even the common courtesy to acknowledge the receipt of either the Draft Bill or letter. The same shabby and unbusinesslike treatment has practically been given to my efforts in favour of increased Direct Representation, the better management of Medical Charities, and my proposed Fund for the Widows and Orphans of Medical Practitioners. Such facts are truly heart-breaking and fearfully discouraging. But among practitioners competition is now so keen and degrading that there seems to be a secret feeling of satisfaction when another practitioner fails; while not a few place one man in an open position and leave him to fight *their* battles as well as he may. Such a "system" must always fail. However, so long as practitioners think it pays them better to be disorganised so long will they agree to accept failure and to appear ridiculous. Again I complain—and, I feel, with just cause—that practitioners have refused to back up my efforts on their behalf financially. No public question to-day can go ahead unless backed up financially. In May, 1896, I sent a circular letter to over 4000 practitioners stating that since 1890 I had advanced money out of my own pocket to the extent of £378 13*s.* 8*d*, and asking that this money should be repaid. Since February, 1896, I have also expended £75 7*s.* 4*d*; or a total of £449 1*s.* Of this total expenditure £81 15*s.* is still unpaid, most of it having been expended in defeating the many Midwives Bills which have since 1890 been introduced into Parliament. From the 4000 practitioners applied to only forty-five replied, these refunding £26 6*s* 6*d*. Now I ask any practical man, Is it fair, is it businesslike, or is it even honest, to allow one practitioner to advance funds required to fight a public Medical question of great moment? I distinctly feel that it is neither fair, business-like, or honest. With other Public questions or in events affecting the interests of a class of persons, a fund for organising and working is always provided. All along I have worked willingly without reward of any kind. But I would urge that if practitioners wish to be considered really in earnest in their demands for improvements they must not be so markedly dilatory in supplying the funds. When it falls upon one to do, not only most of the uphill fighting, but to beg for money to carry out work, the position is little short of personally humiliating while it degrades the cause.

My second reason for resigning is—that so long as there are only 5 Direct Representatives in a Medical Council of 30 Members we shall fail to obtain our just requests. I recognised this as far back as 1890, when I brought this proposed increase up before the annual meeting of the British Medical Association, and when Sir W. Foster and Mr. Wheelhouse took the question before the Medical Council. Five votes against 25 must for ever fail to carry the question of increased Direct Representation. Every person will recognise this except Medical Practitioners. My only regret now is, that Mr. Wheelhouse and Sir W. Foster, and the three other Direct Representatives did not then resign and go to the Profession again and again for re-election, thus putting the Medical Council to the cost and trouble of repeated half-yearly elections, and until the other 25 Representatives recognised the just nature of our request.

My third reason for resigning is that the funds of the Medical Council are much too small to allow the Council to administer the Medical Acts, the Dental Act, and the other Acts relating to Medicine. The average annual income of the Medical Council is about £8000, while the income of the Branch Councils of Scotland and Ireland are so small that these Branch Councils are debarred from doing any practical work. The income of the Medical Council in 1896 was £8746 and its expenditure £10,273. Now what does this mean? It means that practitioners must lay aside their traditional policy of meanness in refusing financial help. My proposal has been, and is, that the Medical Registration fee be made an *annual* one and that each practitioner must pay an annual fee of £1. In 1896 there were 34,478 practitioners, names upon the British Medical Register. Here is a wise and just method of raising over £34,000 per annum—a by no means too small a sum when we consider the vast amount of

Digitized by Google

work which the Medical Council, and more especially its 3 Branch Councils, may and could perform. Even the one item of Inspecting and visiting all of the Examinations held by the 18 Medical Examining Bodies could not be efficiently carried out at a less cost of about £8000 per annum. At present about £500 per annum is expended, and up to now some of these examinations have never been inspected at all! Yet practitioners growl at a policy which is directly due to them. I do not exaggerate when I say that if the Council met 4 times yearly it would on, its present income, be bankrupt in a few years. Will practitioners work out this proposal? It is for them to decide. Finally, I deeply regret the above conditions, which have driven me to resign my position upon the Medical Council. But if my resignation does some little good by calling practitioners to the reasons why, to my mind, efficient work can not now be carried out, then this resignation will not have been thrown away. Many years of close work have given me a fair grasp of the chief Medico-Political and Medico-Ethical questions which now stand in our way. It was my intention from time to time to publish pamphlets upon these questions—but practitioners by their stingy support have ruled it otherwise.

Since 1884 I have carefully prepared pamphlets in manuscript upon following leading questions:—

Name of Subject.	No. of Foolscap Paper.
(a) The better management of our Voluntary Medical Charities ...	94
(b) Proposed Public Medical Services of England	28
(c) Home Hospitals	6
(d) Hospital Management in New Zealand, France, &c.	22
(e) Should workhouse infirmaries be open for Clinical Instruction of Students?	10
(f) Resident Halls for Medical Students	8
(g) Proposed increase in the number of Direct Representatives ...	45
(h) Reforms in the British Medical Association	50
(i) Registration of Stillborn Infants in Denmark, Holland, Switzerland, Sweden, Norway, Russia, Greece, Italy, Spain, France, Belgium, Germany, Austria, America, and Canada	16
(j) Proposed registration of Still-born infants in the United Kingdom	28
(k) Some of the Systems in Force in Foreign Countries relating to the Certification of the Fact and Cause of Death and of the Identity of the Dead	23
(l) Proposed amendment of the Births' and Deaths' Acts in the United Kingdom	56
(m) Proposed amendment of the Births' Acts	9
(n) Proposed Fund for the Widows and Orphans of Medical Practitioners	97
(o) Rules relating to Public Meetings, Parliamentary Debate, and Procedure at Meetings	53
(p) The unrestricted sale of Poisons and dangerous drugs by Chemists	28
(q) Continental laws against prescribing Chemists and dispensing Medical Practitioners	20
(r) Proposed amendment of the Medicine Stamp Acts	23
(s) Penal Powers possessed by Medical Authorities in the United Kingdom against those who practise medicine without being lawfully qualified	95
(t) Similar Penal Powers possessed by Foreign Countries	31
(u) Penalties against those who illegally act as Clergy, Barristers, Solicitors, Chemists, Veterinary Surgeons, Pilots, Mercantile Marine Masters, Engineers, &c.	22
(v) Translation and Collection of the Medical Acts of Italy, Ontario, Manitoba, Nova Scotia, France, Switzerland, and of the United States, Cape of Good Hope	90
(w) The last important work which I have just had translated for me is "The Prussian Tariff of Fees for Physicians, Surgeons, and Dentists established by the German Law of May 15th, 1896," by Dr. A. Forster, Privy Councillor of the Prussian Minister of Medical Affairs	70
(x) Proposed Amendments to the British Medical Acts	...(Unfinished)

I would here state that I shall be glad if practitioners will refund me the above £81 15s. (I was advised to remain upon the Council until the fees repaid this sum. As this would have taken about two years useless time I refused.) Further, I am willing to have any of the above manuscripts published if practitioners will agree to pay further publication. I often regret we have not a society similar to the Sydenham Society and which would publish from time to time original works and transactions bearing upon Medico-Political and Medico-Ethical Subjects. The two I should like published just now are (a) Proposed increase in the number of Direct Representatives, with the provision for an annual Registration fee of £1; and (b) my proposed Widows and Orphans Fund.

Liverpool, Nov. 14th, 1897. ROBERT R. RENTOUL.

"A NOTE ON CYCLING."

To the Editors of THE LANCET.

SIRS,—The able letter of Mr. Harry Campbell, M.D. Lond., in reference to the proper position to be assumed by riders when cycling raises a question of considerable importance. It is directly opposed to the statements in your columns on March 2nd, 1895, of Dr. Herschell, who said: "The stooping posture so habitual to the modern cyclist by contracting the chest prevents the proper expansion of the lungs, and by interfering with the proper aeration of the blood causes the condition of breathlessness to come on quicker." My object in writing to you is to say that my opinion, after considerable experience with riders of both sexes, is that what is needed upon a cycle is a rest for the back attached to the rear of the saddle, which would enable riders who agree with Dr. Herschell, or who find for other reasons, or medical advice, that a stooping posture is injurious to them, to ride perfectly upright, because of the support to the back, and yet avoid some of the objections suggested by Dr. Campbell; also it would make it possible for any rider to adopt the upright position at intervals without injury, which plan, to my mind, presents the true solution of the problem. A rest of this description has been designed and applied and was recently exhibited to the military cyclists at Woolwich. It is called the "Paraclete Back-rest," and when not used as a support to the body can be turned down to form a mud-guard. On the Continent almost all cyclists, male and female, adopt the stooping posture, but whether this is with the consent of their medical advisers I cannot say. I am, Sirs, yours faithfully,

JOSEPH OFFORD.

Gloucester-road, South Kensington, Nov. 15th, 1897.

"MEDICAL EVIDENCE AT CORONERS' INQUESTS."

To the Editors of THE LANCET.

SIRS,—In the leading article in THE LANCET of Nov. 13th and in the previous references to the recent inquest at Twerton, Bath, one point, I think, has not been touched upon—namely, the desirability or not of resident officers of hospitals being allowed to give private advice and evidence in cases that have no connexion with their hospitals. In the present instance it does not appear that the deceased had anything to do with the hospital either as an in- or out-patient. There is, I believe, a rule in most hospitals to the effect that resident officers must not engage in private practice but devote their whole time to the interests of the hospital. If such were not the case what is to prevent them from practically competing with their own staff if asked by some outsider to give expert evidence which certainly seems to be reversing the order of things and, I should think, is a very exceptional occurrence. I am, Sirs, yours faithfully,

Nov. 16th, 1897. G. P.

"THE ARMY MEDICAL STAFF."

To the Editors of THE LANCET.

SIRS,—Your admirable article on the Army Medical Staff should earn the thanks of everyone. There is, however, one statement quoted therein which is so often put forward by the opponents of reform that I should like to emphasise its fallacy. It is this: "The whole *raison d'être* of the combatant officer is to command, fight, and kill in order to defeat the enemy, whereas the *rôle* of the medical officer is to save life and to succour the sick and wounded. Consequently simple military titles for medical officers would be false and misleading and somewhat inconsistent with the dignity of the medical profession." This statement is as much out of date as bows and arrows. In the first place, Army Service Corps officers, whose functions are those of commissariat and transport, are now "combatant officers," and Army paymasters, who remain at home and keep the accounts, have military titles and fighting and killing have no part whatever in their *raison d'être*. Secondly, the medical officer's *rôle* is by no means so purely humanitarian as is here represented. One of his chief functions is to remove sick, wounded, and non-effectives from the front in order that fighting and killing may be more expeditiously proceeded with; and the succouring of sick and wounded is largely for the purpose of restoring them as soon as possible to their places in the fighting line. There is nothing more false or misleading about Captain A, Army Medical Corps, than there is about Captain B, Royal Engineers; Captain C, Army Service Corps; Captain D, Army Pay Corps; Captain E, Army Schoolmaster; Captain F, Army Riding-master; or

Digitized by Google

Captain G, Quartermaster, Army Medical Staff; the latter by the way, actually commanded by the medical officer.

With regard to the dignity of the medical profession it is amusing to observe the solicitude manifested by certain military writers on that score. Although we can assure our friends that they need not be the least concerned about the dignity of our profession we may point out that that dignity is scarcely likely to suffer in asking for reforms which are necessary for the well-being of the army, and that there is no other way than that which we propose of giving the medical officer "the rank and power" which his grave responsibilities necessitate. It cannot be too strongly emphasised that the army medical officer is a soldier as well as a doctor, and in order to carry out his medical duties properly he must have his military position fixed and defined. Combatant officers are fast coming to see the fairness of the claims put forward. The real opponents to reform are the "military advisers" of the War Office.

I am, Sirs, yours faithfully,

Nov. 16th, 1897. M.D.

THE EPIDEMIC OF TYPHOID FEVER AT LYNN.

(FROM OUR SPECIAL COMMISSIONER.)

(Concluded from p. 1282.)

THE drainage of Lynn has from time immemorial been the fundamental problem on which the very existence of the town depended. According to ancient records there is reason to believe that Lynn was founded by the Romans in the reign of Nero. They brought over a number of Belgic or Batavian colonists and set them to work to drain the land on the banks of the Ouse. The spot where the majority of these colonists established a settlement was called Len or Lyn, which is the Celtic word for fen or marsh. From the time of Edward the Confessor to the reign of Henry VIII. the town was dominated and exploited by ecclesiastical authorities, but with the advent of the Reformation the commercial element became predominant and Bishop's Lynn was converted into King's Lynn. This change was favourable to the material interests of the town. For instance, it was paved all over in 1546. In spite, however, of various improvements Lynn suffered severely from plague in 1574 and 1584. There was another terrible epidemic in 1598, when 320 persons were buried in St. James's Churchyard. In 1636 there was again a great plague and no market could be held. So it seems that in the past, as in the present, the inhabitants of Lynn had their full share of sickness. The town became renowned for the manufacture of agricultural implements and of oil-cake, but the want of drinking water caused great distress till the year 1423. Henry VI. then gave powers to cut a canal to the Gaywood River at "Kettle Mills." In the fifteenth century the water of this river was considered to be very pure, and doubtless with the sparse population of those days there was no great risk of pollution. Under Cromwell the water canal was carefully cleaned out and a larger supply provided. Strange to say, the keepers of alehouses alone were made to pay the cost of this improved water-supply; thus it was the consumption of alcohol that helped to promote the cause of temperance. But the water came in an open ditch, which was very objectionable, and a great progress was achieved in 1699 when wooden pipes were introduced. Subsequently a water-wheel was constructed as were three pumps to raise the water to a reservoir, so that it might be delivered by gravitation. Horse-power was also utilised, and this continued till 1829, when a water-tower and tank were erected, and a steam-engine (instead of water and horse-power) was employed. At the same time iron pipes were substituted for the wooden pipes. The water, however, was only delivered in cisterns at the basement of the houses and had to be raised by hand-power to the upper floors. There were also many persons who still took their water from wells or from open ditches.

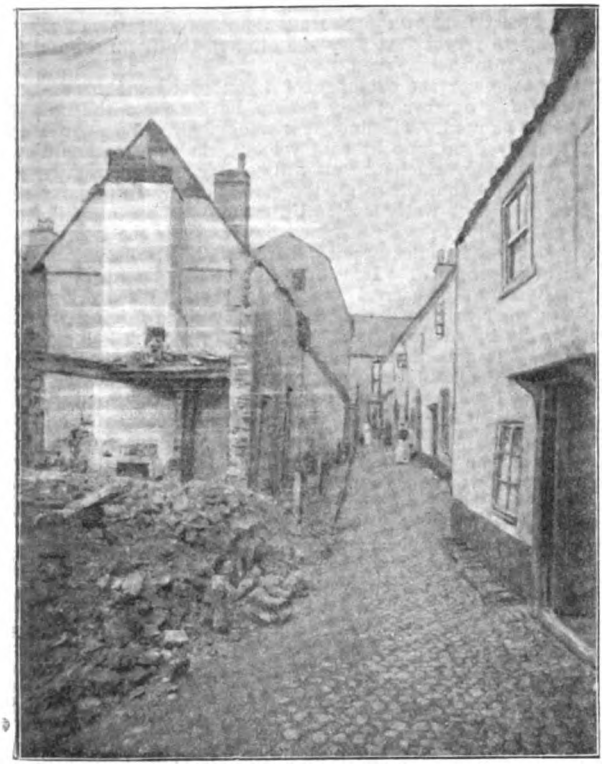
Though there have been constant difficulties with regard to the supply of water fit for drinking, this was not due to a mere want of water. On the contrary, up to the year 1821 Lynn had constantly suffered from disastrous floods. At that date, fortunately, the channel of the river was deepened for a distance of several miles. These excavations were called the "Eau Brink," and when they were terminated it was possible to lower such sewers as existed, and the basements of many houses thus became somewhat dryer. Some thirty years later a vast surrounding tract of land was redeemed from the sea. As these general drainage works progressed ague or malaria which was endemic in the town and surrounding country gradually disappeared, though it generally showed a marked increase just at the moment when the soil was disturbed by the digging of fresh trenches or drains. Apart from the general drainage of the soil, which is a problem affecting the entire fen district, there is the question of dealing with the Lynn sewage. A scheme for this purpose was prepared in 1887 by the former borough surveyor (Mr. E. G. Mawbey, Assoc. Inst., C.E.), which, by proposing one single outfall, made it very difficult to obtain sufficient gradients in so flat a town as Lynn. At present there are short sections of brick sewers discharging at the nearest point in the River Ouse or in its four "fleets," the little tributaries that pass through the town. For the northern and eastern part of the town a large egg-shaped brick sewer was built which, having its outfall near the old dock, is known as the "dock culvert." It is ventilated by openings on the street level and by a few shafts carried up to the roofs of houses. Though there are several automatic flushing tanks at the heads of branch sewers it cannot be said that these sewers are self-cleansing. Then when the tide comes up, there is no out-flow, and the sewage remaining stationary for several hours must make deposits. It is noticed also that when the wind is from the west, and therefore blows into the mouth of the dock culvert, very unpleasant odours escape from the ventilators. Fortunately, many of the sinks and the closets are not inside the houses, but in outer buildings, and there has been much improvement of late in respect to the ventilation of private drains. It is quite a common sight at Lynn to see the soil-pipes continued above the roofs of the houses. This is a most necessary precaution, for the sewers certainly constitute a grave danger to the health of the inhabitants. The worst sewer is the dock culvert. It is a large and dirty sewer, and it receives half the drainage of the town. Dr. Bruce Low, in his report to the Local Government Board on the typhoid fever epidemic of 1892, relates that out of forty-one of the earliest houses invaded twenty-seven were in the area served by the dock culvert. This area had a population of 10,300 inhabitants, but only twelve of the houses where there were cases of typhoid fever drained direct into the culvert, the remaining fifteen houses had privies. In the area not drained by the dock culvert there were seven houses with water-closets and eight houses with privies where typhoid fever occurred. As the population of the latter area was 8800 this makes a proportion of 1·7 per 1000 houses in which cases of typhoid fever were notified. This calculation of course deals only with the forty-one first houses that suffered. On the other hand, the proportion of houses per 1000 in the dock culvert district was equal to 2·6 per 1000. It is true the houses with privies supplied the greatest number of cases. But whether a house has a privy or not it still feels the effects of the sewer that passes close by. There are the street ventilators and also the drainage of the yard, the rain from the roof and the sinks, which does not go into the privy but into the sewer. The houses with privies do not escape sewer contamination; they only add to it by a little private contamination of their own which arises from their privy and which helps to accentuate the evils due to the sewer.

After the epidemic of 1892 the borough engineer, Mr. E. J. Silcock, C.E., was instructed to examine all the sewers of the borough; and out of 140 streets he found that the sewers were defective in no less than 72 streets. These sewers possessed one or several of the following defects: they were either insufficiently large in sectional area or not sufficiently deep to drain properly the surrounding property, or they were not laid to proper lines and gradients, or they were brick sewers in bad condition and did not possess suitable manholes for inspection, or they were deficient in ventilation and in flushing arrangements. Finally, there were so many outfalls that it was impossible to describe the arrangement as a "system." Mr. Silcock was then invited to prepare a scheme, and this he has done on the principle that the first object is to drain the town properly and that the outfall is a matter of secondary importance. When a town is flat and not prepared to incur the expense of raising the sewage by artificial means there

Digitized by Google

is but one method of obtaining sufficient gradients in the sewers, and that is to have, not one system, but several systems; not one outfall, but several outfalls. This is, indeed, what nature itself has done in Lynn. The town is divided by four little rivulets, or "fleets" as they are called by the inhabitants, and the natural drainage is towards these streams. Mr. Silcock proposes to convert the four streams into four main collectors. The four districts thus drained being small the sewers would be short, and therefore it would be possible to dig deep enough to give them the required gradient. The only objection is that there would be four outfalls discharging the sewage into the river abreast of the town. As the river is a tidal river, does not pass before another town, but at a short distance from Lynn falls into a broad arm of the sea—namely, the Wash—it is thought that there is no need to purify the sewage. In any case, if such a necessity should ultimately arise a deep intercepting sewer could be constructed parallel with the river, which would receive the sewage from the four outfalls and convey it to a sewage farm or to purification works.

The necessity of dividing the town into four drainage areas is due, not merely to the flatness, but also to the nature of the soil. The soil is so unstable that it would be difficult to build large and deep-laid sewers. Near the gasworks to find a solid foundation for a chimney four borings were made twenty feet from each other and thirty-six feet deep. The result was different for each boring, though they were so near one to the other. Sometimes it is necessary to go down as far as forty feet to reach a really stiff clay. The clay that is near the surface is a silting or greasy clay and it is constantly varying in thickness. Most of the buildings in Lynn have settled through a partial subsidence of the foundations. Then there is the great difficulty of dealing with the rain-water, for the sewers must not only drain the water away but provide a sufficient storage capacity when the outfalls are blocked by the rising tide. In deciding what should be the size of the sewers it does not suffice to know the maximum rainfall noted in twenty-four hours, but rather the maximum noted in less than an hour. Thus it has rarely happened that more than two inches have fallen in a day, and this, if evenly divided, would only mean one-twelfth of an inch in an hour, a quantity that could be easily disposed of by small sewers. But it often happens that during a storm an inch of rain falls in less than an hour, and even that has at times been largely exceeded. Thus on Sept. 27th, 1893, no less than 1·45 in. of rain fell at Lynn in twenty-five minutes, which is equal to a rate of 3·5 in. per hour. Nevertheless, a consultation of the existing records indicate that it is very rare indeed that more than one and a half inches fall in an hour. The present scheme of drainage is based on this supposition. Further, observations made in numerous towns show that on closely built and paved areas only 50 per cent. of the rain which falls finds its way into the sewers while the rain is falling. Therefore the sewers will be planned to take three-quarters of an inch of rain per hour, and this will be equal to an actual rainfall of one and a half inches in the hour.



Storm overflows, which, according to the above calculation, would rarely come into use, will be constructed so as to communicate with agricultural drains that are outside Lynn and under the control of the Norfolk Court of Sewers Some difficulty has been experienced in prevailing upon this latter authority to assent to this scheme. Their purpose is to prevent floods, and now it was proposed to flood them with the overflow from the Lynn sewers. In answer to these objections it was pointed out that by the time the storm overflows began to act the sewage would be so diluted as to be fit to be thrown even into a stream containing fish. Secondly, that the Lynn overflow would occur immediately and while the storm was at its height. Agricultural and marshland drains which are connected with a very extensive rural district do not feel the effect of a storm at their outlet till many hours after the storm is over. Consequently, even if the tide was rising when the storm occurred there would be time for the overflow from the Lynn sewers to escape before the water from the agricultural districts came down. Nevertheless, before the Norfolk Court of Sewers would consent to the proposal the Lynn Town Council had to promise to pay damages if a flood was occasioned by their storm overflows, but the onus of proof would lay with the Norfolk Court of Sewers. The only chance of an accident of this sort would be if two very violent storms occurred in succession. In that case the water from the first storm might have reached the outfall of the drains under the Court of Sewers at the moment when the overflows from the Lynn sewers were bringing the waters of the second storm. If, also, just at this moment the tide was rising and the outfalls were consequently blocked, then the Norfolk Court of Sewers might have cause to regret that they had allowed the Lynn sewers to overflow into their system.

The scheme for the drainage of Lynn involves the construction of a number of new sewers, but some of the old ones could be used. The flow, it is calculated, will be equal to 3 ft. per second, and at that velocity the sewers should be self-cleansing. Such a result will be very good, especially in a town like Lynn, where all the sewers must of necessity be below the high-water level. Unfortunately this principle cannot be applied in every instance, but it will be the general rule, and where it is not applied there will be special means of flushing provided. It is also promised that an effort will be made to compel property owners to relay and ventilate their private drains wherever these are defective. Such, in its broad lines, is the scheme for the redrainage of Lynn. It was first submitted to the sub-committee of the Town Council Sanitary Committee. When it had been approved by the sub-committee they converted the Sanitary Committee, and the latter in turn appealed to the whole council, which ultimately and unanimously endorsed the scheme. At the same time it was decided to apply for a paving as well as a sewage loan. In response to this demand the Local Government Board opened an inquiry on both proposals at Lynn on Dec. 19th, 1894. It was soon evident that there was strong opposition on the part of the ratepayers and that they could not all be heard on the same day. The curious point was that several of the ratepayers who had fought against the new water-supply scheme and argued that the old water-supply was good but that the sewers were bad, now came forward to protest against the new drainage scheme. The Local Government Board, on its side, insisted that every detail should be settled before sanctioning the scheme, and there was the difficulty with the Norfolk Court of Sewers described above. Their land is below high-water mark; they are also tide-locked and subject to floods; and now it seemed as if the town of Lynn, by its proposed storm overflows, wanted to increase their floods. In exchange for this threatening prospect the town of Lynn had nothing to offer. Such an unequal bargain could not be negotiated in a day, and that the matter has been satisfactorily settled according to the terms already mentioned is in itself a good enough result, and it is hardly fair under such difficult circumstances to complain of the time it took to bring it about. It must be borne in mind that in these rural districts there is a tendency on the part of country people to look upon a town as an infringement upon their rights. In fact, to judge from the attitude of some rural magnates, it would seem as if they thought that a town ought not to exist at all, and if it does exist it should keep itself very quiet. In this instance not only did the town of Lynn fail to keep quiet, but it persisted in having unwelcome epidemics, and now actually wanted to pour out its foul and contaminated sewage upon the sacred precincts of a purely rural district. Then, to further embarrass the rapid progress of negotiations, which, under the above conditions, gave so little promise of success, the Norfolk Court of Sewers only meet twice a year. Fortunately they appointed a sub-committee with which it was possible to negotiate, but the committee had no authority to act.

In view of these obstacles the Local Government Board inquiry was adjourned. The Local Government Board at first raised some objections to the many outfalls, and finally contented itself by insisting on the prolongation of one of these outfalls, though this will involve an extra expenditure of £5000. The Lynn Town Council made fresh applications for a sewage loan in May, 1895; but this could not be granted because the drainage scheme involved the covering over of one of the fleets, which cannot be done without an Act of Parliament; and it also required the consent of the Norfolk Court of Sewers for the storm overflows which were to communicate with their system of drains. It took two years to secure these objects. The Bill in Parliament was carried in 1896 and received the Royal consent in the middle of that same year. The negotiations with the Norfolk Court of Sewers were not terminated till May, 1897. The Local Government Board was now able to sanction the loan, and this was done in the following July. The estimated cost of the drainage scheme, which is now at last sanctioned, is £27,500. The repaving

Entrance to Desolation-court.

of the town will cost £17,690, and the new water-supply, which should be ready for distribution in six months, is estimated at £30,000. The town has thus to incur an outlay of £75,190.

It is a great pity that no effort is made to profit by the stress of the present epidemic to raise the loans for sanitary improvements from the £75,190 now sanctioned to a round sum of £100,000. Something might then be done to deal with the slums of Lynn and a public abattoir could be constructed. Here, as in so many other towns, the private slaughter houses are a danger and a nuisance. Then there are some very melancholy courts and alleys in Lynn. A scheme for dealing with two such areas has been prepared, but nothing came of it. One of the areas has been nicknamed Desolation-court. It is bounded by Bridge-street, All Saints-street, Union-street, and Crooked-lane. The houses are so old as to be very dilapidated, but not old enough to be picturesque. There are in Lynn many mediæval houses, which, though in a sorry condition, it would be an act of vandalism to destroy. No amount of money could rebuild these interesting and picturesque mementoes of a past era; therefore no pains or expense should be spared to clean, repair, and fortify them so that they may long continue to render the town interesting, to attract visitors, and to bear witness to the sound work of our forefathers who lived in the days when jerry-building was unknown. But in Desolation-court the cottages are not picturesque—they are simply extremely unhealthy. Many of them have no back windows at all. If the owners were to pull some of these cottages down the courts are so crowded and cramped for room that they could not, in rebuilding the cottages, comply with the by-laws fixing the minimum amount of space that must be given both in the front and at the back of all newly constructed dwellings. On the other hand, some of the cottages are so dilapidated that it has been impossible to patch them up. Therefore there are houses in this area that cannot be inhabited such is their ruinous condition. In some instances the cottages have completely collapsed and a mound of bricks alone indicates the spot where they formerly stood. In other instances the outer walls are still standing, but the roofs and floors have gone. It is these melancholy ruins and the rickety appearance of such houses as still remain standing which gives to the area the appropriate appellation of Desolation-court.

One of the accompanying illustrations from photographs (Fig. 1) shows an entrance to this area. On the right side it will be seen how the wall of a cottage bulges out in the lower portion, while the cottage facing it has completely collapsed. In the other illustration (Fig. 2) there are more ruins in the foreground, and we see a front view of two cottages. It will be observed that the roofs are not straight, but are beginning to curve inwards, and that one window especially is totally out of line. It will also be seen how the staircase abuts right on to the street or alley. There is neither landing stage nor entrance passage. The steps have given way and are not straight or level. These illustrations, though reproduced from photographs taken under the adverse influence of November fogs, may help to illustrate the dilapidated and worthless condition of this property. After visiting such localities is it difficult to avoid

Fig. 2.

View in Desolation-court.

Digitized by Google

smiling sadly at the posters issued by the town council earnestly inviting all the inhabitants to boil their water. The dwellers in these slums are too often without the means of making a fire to cook their dinners, let alone the boiling of their milk and their water. Anything like effective precautions seems impossible in the midst of such misery, and these courts and alleys have paid their full tribute of victims to the epidemic. Fortunately, the collapse of some of the houses has given more air-space, and this improves the condition of the dwellers in those houses that are still standing. The second area of the town which it was proposed to condemn is at the opposite extremity—namely, the north end. Here the houses are not so dilapidated. Probably they are not so old, but they are small, overcrowded, and cramped together. In the absence of ruins there is less breathing space, and their general appearance conveys an impression of wretchedness and squalor. Such spots may well become hotbeds of disease.

In conclusion, it is necessary to insist that the work of sanitation is complex and that the causes of typhoid fever are numerous. The securing of a pure water-supply is the first and the most necessary of all sanitary measures, but it is not the only indispensable reform urgently needed at Lynn. Seeing that the water-supply of Lynn is exceptionally foul and liable to contamination the water question should come first; but it would be a fatal error to suppose that the town will be safe when once a pure water-supply has been provided. The drainage of the town is at least second in importance, and this question of drainage should comprise not only the removal of sewage, but the purification of the subsoil on which the town stands. The courts and alleys must be so repaved as to prevent any foulness reaching the subsoil. Then some of the worst slums have to be demolished, and energetic measures taken to secure the wholesome rehousing of the poor. Nor is this all; the health of Lynn will depend in a measure on the health of the surrounding agricultural districts. Already there have been within the last few weeks three cases of typhoid fever in neighbouring farms which supply milk and butter to the town. Measures were taken to prevent mischief arising from this source of contamination; but the danger may arise before proper precautions can be enforced. In the larger farms and dairies that send milk to London the organisation is more perfect, the sense of responsibility greater, and a strict surveillance is more easy to establish. It is in small, petty farms that the principal risk arises. In many of these rural districts the water-supply is most defective, but there is no money to procure a better supply. Yet something should be done, and the question arises whether the distant consumers of the produce of these poor rural localities might not contribute something towards the expense of measures which will protect them from the danger of infection. It is a very difficult but also a very urgent question. If as a result of the present epidemic these matters are taken earnestly in hand the victims will not have suffered in vain.

THE RINDERPEST IN SOUTH AFRICA.

(FROM A CORRESPONDENT.)

(*Concluded from p. 1285.*)

Professor Koch's Researches.

WE now come to the consideration of Professor Koch's work on rinderpest. An experimental station was established about two miles out of Kimberley, the floors and buildings of the old Victoria Diamond Mining Company having been placed at the disposal of the Government by the De Beers Company. Here Professor Koch commenced his valuable investigations on the disease on Dec. 5th, 1896. The results of his labours may be conveniently divided into two heads: (1) those referring to the etiology or causes and general characteristics of the poison; and (2) the methods of rendering cattle proof against its effects.

We will consider first that portion of his work which comes under the first heading. (*a*) The most careful and advanced microscopic and bacteriological methods of examining the blood and tissues failed entirely to detect any specific organism as the cause of the disease such as is present in the blood and tissues of animals suffering, for instance, from anthrax. (*b*) Other experiments were instituted to endeavour to discover how long the blood and tissues retained their infective properties. From these it appeared that any form of infected material taken from an ox which had died from rinderpest lost its power of communicating the disease to healthy animals if kept in a dry atmosphere at the ordinary temperature for about fourteen days. Putrefaction was also proved to destroy the poison. The conditions that obtain in the veld are not exactly similar to those under which these results were obtained. Experience, however, in affected areas shows that the poison is very soon destroyed, especially in dry weather. In damp weather or in places where the infected material is protected from being thoroughly dried it retains its poisonous properties for a longer period. Cattle kraals retain the poison longer than the open veld, and on this account when it is desired to destroy all infection rapidly it has been found wisest to burn the kraals down. We still need further evidence before being able to state definitely when an area which has once become infected will be again safe for ordinary healthy cattle. A few months at the outside is, however, the probable limit. (*c*) As to the distance through which the poison can be carried in the atmosphere the experiments of both Professor Koch and Dr. Edington, with those of other investigators, conclusively prove that the poison is carried but a very limited distance, if at all, in the atmosphere. Professor Koch had his experimental animals standing about twenty feet apart, separated merely by two sheets of galvanised iron, and in no instance did he find that the infection was communicated from affected to healthy animals provided that the attendants and utensils were kept entirely separate. Mr. Hutcheon's own experience on the Molopo River indicated strongly that the disease was not conveyed very far in running water. (*d*) Another important point in regard to the poison was the extreme virulence of rinderpest blood in conveying the disease. Professor Koch found that the hypodermic injection of $\frac{1}{10}\frac{1}{0}$th cubic centimetre of rinderpest blood, roughly about $\frac{1}{3}\frac{1}{0}$th of a drop, was sufficient to produce the disease in a healthy ox, and Dr. Kohlstock, by later experiments, proved that half this quantity—i.e., about $\frac{1}{6}\frac{1}{0}$th part of a drop—of rinderpest blood when injected into a healthy ox produced a violent attack of the disease. (*e*) As to the effect of the poison on sheep and goats, by passing the poison through successive series of sheep it was found that the poison became more powerful, although these animals did not appear themselves to suffer from marked symptoms of the disease with the exception of a rise of temperature. Blood, however, taken (after the virus had been passed through five series of sheep) from them and injected into healthy oxen produced a very violent and fatal form of rinderpest, leading to the conclusion that the poison by passing through these animals becomes more powerful. This fact possibly helps to explain why on some farms in close proximity to one another the percentage of recoveries varies so greatly. It would also account for the fact that in some few cases the sheep and goats have died from the effects of the disease. In the case of goats the virus appeared to become weakened. (*f*) The mixture of glycerine or phenol with rinderpest blood destroyed its infective properties. To recapitulate, the results of Professor Koch's experiments may be thus summarised: (*a*) That no specific organism has been proved to be present in rinderpest; (*b*) that this poison is rapidly destroyed when exposed to a dry atmosphere at a moderate temperature; (*c*) that it is only conveyed a very short distance, if at all, by the atmosphere; (*d*) that $\frac{1}{10}\frac{1}{0}\frac{1}{0}$th cubic centimetre, or about $\frac{1}{6}\frac{1}{0}$th of a drop of rinderpest blood, is sufficient to communicate the disease when injected in a normal saline solution (6 per cent.) into a healthy ox; (*e*) that the virus appears to be rendered more powerful by passing through successive sheep, but weakened when passed through successive generations of goats; and (*f*) that phenol (carbolic acid) in weak dilution destroys the poison and glycerine has the same effect.

We now come to a second division of Professor Koch's work—viz., the methods which he discovered for rendering cattle proof against the poison. Two methods for rendering cattle immune against the disease were discovered by Professor Koch, and it is as well to point out that the whole of the subsequent work which has been reported by various observers is little more than either a repetition of his original experiments or consists in improvements which experience and further experiments have added to the methods of preparing the materials or in applying them. The two methods of rendering cattle immune discovered by Professor Koch are known as (1) the serum treatment and

Digitized by Google

(2) the bile treatment. First, as regards the serum treatment. Professor Koch proved that the serum of cattle which had recovered from an attack of the disease (salted cattle) when injected under the skin of healthy cattle protected them from the poison of rinderpest for a short time, the immunity probably not lasting more than twelve, or at the most twenty, days. He then mixed ninety-nine parts of serum from salted cattle with one part of blood taken from rinderpest cattle and kept this mixture in an ice-closet for one night, and then injected 20 c.c. into healthy cattle, with the result that in a fortnight he immunised several cattle to such an extent that they were able to withstand an injection of 20 c.c. of rinderpest blood, and $\frac{1}{100}$th part of this is a fatal dose to ordinary healthy cattle. The immunity thus produced is probably equal to that of an animal which had contracted, and recovered from, the disease. With regard to the serum treatment, it appears that other observers in Russia had stated that serum from salted animals was protective, but Professor Koch was the first to put it to any practical use and to publish the methods. Secondly, the bile treatment. This was an entirely original discovery by Professor Koch, and promises to be an incalculable boon to the cattle-owners of the colony and other parts if only properly carried out. He injected 10 c.c. of bile (taken from cattle which had just died from rinderpest, or which had been killed about six days after they had been purposely given the disease) into healthy cattle, and discovered that after fourteen days a quantity of rinderpest blood (sufficient to have given the disease to any number of healthy cattle) could be injected into them without any injurious result. Subsequent experiments proved that this immunity, or power of resisting the poison, was established at latest on the sixth day after the injection of the bile. Animals which became infected with the disease four days after the injection of bile, although contracting the disease, recovered from it after a mild attack, thus showing that the immunity commenced about the fourth day after the bile injection. Cattle which had been infected with rinderpest before the injection of bile, or at any period before the fourth day after the injection, died from the disease, thus proving that, in order to obtain good results, it is necessary that cattle should receive the bile treatment before the disease has broken out amongst them. This fact cannot too strongly be insisted upon, and has been amply proved by subsequent experience. The local result of an injection of bile from a rinderpest ox into a healthy ox is a hard, somewhat painful swelling of the size of a man's fist, which gradually disappears in the course of a few weeks. The development of this swelling is a fairly certain sign that the inoculation has been successful provided it does not suppurate, in which latter case the result is uncertain, the process of suppuration being liable to destroy the immunising properties of the bile. Subsequent experiments by Professor Koch, and also by Dr. Kohlstock, proved that the bile used by them was absolutely incapable of giving the disease. The experience, however, of Mr. Hutcheon and his staff appears to prove that some biles are actually capable of communicating the disease. As to the duration of the immunity thus produced no definite time can be at present stated. Dr. Kohlstock proved that it is as powerful at the end of three months as it is a fortnight after the injection, and it appears that the immunity lasts for a period long enough for all practical purposes.

Dr. Edington's Glycerinated Bile.

Next may be discussed the improvements which subsequent observers have added to Professor Koch's original methods. One of the chief obstacles in the application of Koch's bile treatment is the difficulty experienced in preserving the immunising properties of the bile when once it had been removed from the bodies of the rinderpest oxen. Dr. Edington has now proved that by mixing one part of glycerine with two parts of rinderpest bile its immunising properties are preserved for some time under ordinary conditions, so that it can now be sent any distance that is required in properly sealed vessels. The addition of glycerine has the further advantage that it affords an extra security against the bile being the medium by which infection is conveyed, for we have already seen that Professor Koch's experiments proved that glycerine is very destructive to the rinderpest poison. It appears, however, to weaken the immunising power of the bile, and it has been found necessary in order to get good results to inoculate the animals about ten days after the injection of bile with virulent blood. This is a distinct advantage, for the experience gained during the last six months in the preventive treatment of rinderpest goes to prove that it is advisable in actual practice, in order to obtain reliable results, that the cattle treated should if possible have a modified attack of the disease. Another point in favour of the glycerinated bile is that all except very watery and putrid biles can be used in its preparation, and consequently a much smaller percentage of cattle have to be sacrificed in its production than under Koch's original method, in which only selected galls can be used.

The following telegraphic report furnished by Mr. Hutcheon gives in a concise form his experience of the methods and results of inoculation in the colony from March to the end of July, 1897: "Since the beginning of March last we have carried out Koch's method of bile inoculation as carefully as practicable in accordance with his directions, but experience has shown that however carefully the bile may be selected and the operation of inoculation performed the results are very irregular and in not a few instances intensely disappointing. The fact is that we are not in possession of a simple practical test to enable us to distinguish between a bile which is both safe to use and permanent in its immunising effects and biles which are either too strong and communicate the disease to the animals inoculated or too weak and do not confer immunity for any length of time. In order to obviate this irregularity we have adopted the method of mixing the biles before sending them out, and in this way hope to secure more uniform results. We have recently, relying upon the experiments conducted by Dr. Edington, adopted his method of inoculating with glycerinated bile, which briefly consists in mixing all clear biles of whatever colour with glycerine in the proportion of one part of glycerine to two parts of bile. This mixture is then kept for eight days before being used, and twenty cubic centimetres are injected in each full-grown animal. It is claimed for this glycerinated bile that it does not communicate the disease as Koch's bile is liable to do, and although we have no means at present of judging of the length of the immunity conferred, as it has only been practised for a very limited time, yet a number of tests appear to show that the immunity which exists on the tenth day is as complete as the immunity conferred by Koch's bile at the same period. Hence it is recommended that in every instance in which the glycerinated bile is used it should be followed on the tenth day by an injection of $\frac{1}{10}$th of a cubic centimetre of virulent blood. In a number of herds experimented on $\frac{2}{10}$ths of a cubic centimetre of rinderpest blood were used for this second inoculation with satisfactory results; less than 2 per cent. succumbed to the test, but a considerable number were somewhat seriously affected. For that reason I have recommended that $\frac{1}{10}$th only should be used, as this dose can be followed at later stage by a larger dose with perfect safety. But while recognising the value of this bile inoculation, that it is the only practical method of carrying out inoculation on such an extensive scale as has now been forced upon us, we are at the same time cognisant of the superiority of what is called the serum treatment, and we are making provision to deal with all infected herds by that method and hope to be able to extend it to all clean herds as the number of highly immunised animals at our disposal increases. Respecting the measures which we have adopted for carrying out the bile inoculation, one or more stations are established in each district for the production of bile. To these stations all cattle-owners are required to bring a percentage of their cattle sufficient to produce bile for the remainder. These cattle are inoculated with rinderpest blood on their arrival at the station, and are kept there until they either die or are killed at the proper time, when the bile is extracted and prepared, and then distributed amongst the farmers for the inoculation of their cattle."

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Annual Report of the Medical Officer of Health of the County of Lancaster.

THE report of the medical officer of health for the county of Lancaster (Mr. Edward Sergeant) shows that the health of the county for the year 1896 has been satisfactory. The number of births registered in the county districts under review for that year were 52,318, corresponding to 28·73 per

Digitized by Google

1000 of the population. There was a marked reduction in the number of deaths as compared with the previous year, the total of which amounted to 31,653. In both urban and rural districts the births of males exceeded those of females. In the urban districts the disproportion in numbers between the two sexes was further increased by a greater female mortality, the reverse being the case in the rural districts. The corrected death-rate for 1896 was 16·61 per 1000, as compared with 18·3 per 1000 in the previous year; while for the seven years 1889–95 the average death-rate was 18·7 per 1000 of the population. Infant mortality shows a considerable reduction, which is mainly due to climatic conditions. In the matter of dairies, cowsheds, and milk-shops the report states that inspections under the Local Government Board order were very unsuccessfully carried out, the conditions of cowsheds in a large number of districts being insanitary. Childwall appears to be a very healthy urban district. Five births and only one death, and that of an infant six weeks old, who died from whooping-cough, were registered there during the year. The birth-rate in Garston was 31·5 per 1000 of the population and the death-rate 14·1 per 1000, a reduction of mortality as compared with the figures of 1895. In this district there was a zymotic death-rate of 2·31 per 1000, whilst the hospital accommodation is complained of as being too limited. The report deals most favourably with the districts of Great Crosby and Little Crosby, not a single case of infectious disease occurring in the latter district in 1896. The death-rate of Prescot was 19·7 per 1000, which, although lower than that of the previous year, might be regarded as much above the average of urban districts, the zymotic death-rate being 3·57 per 1000. In Skelmersdale the birth- and death-rates both show a reduction as compared with the previous year equal to 4·7 and 2·5 per 1000 respectively. There was an increase in the zymotic death-rate and the proportion of infant deaths to births rose considerably. The birth-rate of Southport was a little lower than in 1895, whilst the death-rate was the lowest ever recorded in that borough—viz., 14·46 per 1000. The zymotic death-rate was slightly higher than in the previous year, and the great preponderance of zymotic diseases in the rural as compared with the urban wards is regarded as most unsatisfactory. Mr. Sergeant points out that in the rural districts the habits of the people in the matter of "unrestrained and reckless inter-communication" greatly favour the spread of infection. In Warrington the birth-rate was 36·8 per 1000, the same as the previous year. The death-rate, 19 per 1000, showed a decided improvement. Measles was very prevalent, causing 63 deaths, against 111 in the previous year. The health of Widnes was, on the whole, favourable, the statistics of mortality showing an improvement on the previous year. Similar reference is made to the two rural divisions of Wigan.

The Hospital Sunday Fund.

The Hospital Sunday Committee, in their twenty-seventh annual report, deplore a falling-off in the Hospital Sunday Fund as compared with last year. On the other hand, the Hospital Saturday Fund showed a steady increase and more than counterbalanced the loss of £330 on the former fund. By the addition of the two funds the grand total was brought up to £11,871 8*s.* 11*d.*, leaving the sum of £11,400, which was distributed among the various medical charities. The Lord Mayor questioned the policy of fixing the Sunday collections for the month of January and felt that the date should be made to approximate more closely to that of the Saturday collection. A difference of opinion, however, prevails on this point. Sunday last was observed in Bootle as Hospital Sunday, and collections were made at the various churches and chapels in the borough and neighbourhood in aid of the funds of the Bootle Borough Hospital. The new mayor (Dr. J. McMurray) attended in his official capacity the morning service at Trinity Presbyterian Church and the evening service at St. Mary's Parish Church. The mayor's procession was one of the largest seen in Bootle for some years past.

Work at the Medical School of University College, Liverpool.

The winter session is now in full swing, the total number of students being about the same as last year. The numbers in the anatomical department are well maintained and the rooms are crowded. The students are working well and there is a plentiful supply of anatomical material. Great progress has been made with the formation of the anatomical collection and a new museum is among the urgent needs of the department. The new outbuildings and macerating accommodation have been of great use, especially during the past four months. Professor A. M. Paterson has been engaged on the dissection and maceration of an Indian elephant, the bones of which have been macerated completely (in sand) in the very short period of four months. Professor Paterson exhibited them on Friday night at the Biological Society. The new laboratories in course of erection are approaching completion and part of the physiological department will be in use after the Christmas holidays. The medical students' annual dinner will take place on the 27th inst.; the chair will be taken by Mr. Rushton Parker, the Professor of Surgery in University College.

Liverpool Medical Institution.

The biennial dinner of the Liverpool Medical Institution was held on Nov. 6th. The chair was occupied by Dr. Caton (the President), who was supported by the Lord Mayor and other prominent citizens. About 140 gentlemen sat down to dinner.

Police Horse Ambulance Service.

The offer of the Watch Committee to provide a horse ambulance day service for the Royal Infirmary, the Northern, Royal Southern, and Stanley Hospitals has been accepted. The hospitals are to provide the stabling. The Watch Committee will also provide a horse ambulance at the central fire station for the night service of all four hospitals and a second at Old Swan for the service of the outlying districts. When this service is completed Liverpool will be in an unique position with regard to its ambulance arrangements, no other town in the United Kingdom being similarly equipped. It will be necessary for the police to purchase three ambulances and six horses. No addition to the police force will be required.

Nov. 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Medical Society, Edinburgh.

THIS society was formally opened on Friday of last week, by an address from Dr. T. Barlow of London. The lecturer discoursed on Infantile Scurvy to a large audience of senior students and a representative body of professors and lecturers. He described the clinical features of the condition and the anatomical changes which occurred in various parts, but more especially in connexion with the bones. He pointed out the association of these. He then argued from the phenomena present and from the effect of treatment that the condition was scurvy and not rickets. He thought that the condition was on the increase, and that it was attributable to the feeding of children on patent foods and on sterilised milk too much diluted. The address was illustrated by a number of diagrams and coloured drawings as well as by preparations in spirit. It was listened to with marked attention and was much appreciated. The vote of thanks was proposed by Dr. Carmichael, the president of the society, and seconded in a very felicitous speech by Professor Fraser.

Aberdeen University.

Mr. George Dean, M.A., M.B. Aberd., has been appointed Bacteriologist to the Antitoxin Department of the British Institute of Preventive Medicine, Sudbury, in succession to Dr. Wm. Bulloch. After graduation Dr. Dean spent some time in Berlin and Vienna, devoting himself mainly to the study of pathology and bacteriology. Since 1891 he has held the posts of assistant to the Professor of Pathology in Aberdeen University and assistant pathologist to the Aberdeen Royal Infirmary; more recently he was also appointed pathologist to the Royal Hospital for Sick Children. As university assistant in pathology he has conducted classes in morbid anatomy and histology and on advanced bacteriology, besides assisting Professor Hamilton in the general work of the department, including the research work in experimental pathology and bacteriology. Dr. Dean has taken a great interest in local medical societies and is secretary of the Aberdeen Medico-Chirurgical Society. His departure from Aberdeen will be a great loss to the medical school and to the profession generally in the north of Scotland. Fitting expression was given by his medical brethren to their high appreciation of his services when they met in large numbers in the Palace Hotel on the evening of the 9th inst., under the genial presidency of Professor Hamilton, to

Digitized by Google

congratulate him on his promotion to a new sphere of work and to present him with a handsome testimonial.

A Complimentary Dinner to Dr. C. O. Hawthorne.

On Nov. 12th, in the Windsor Hotel, Glasgow, a complimentary dinner was given to Dr. C. O. Hawthorne on the occasion of his leaving Glasgow. The attendance numbered about ninety, and was of a representative nature, among those present being Professor McCall Anderson, Professor Murdoch Cameron, Dr. Yellowlees, Dr. Wallace Anderson, Dr. Alexander Robertson, Dr. Lindsay Steven, Mr. Henry Clark, Dr. Middleton, Dr. Newman, Dr. Allan, and Mr. Henry Rutherfurd. Over forty apologised for their inability to attend, including Professor Cleland, Professor McKendrick, Professor Coats, Professor Ferguson, Professor Bower, and Dr. Hector Cameron. In their letters, and especially in the speech of Professor W. T. Gairdner, who was in the chair, there was evident a feeling of very sincere regret that Dr. Hawthorne was about to leave Glasgow, and that his valuable and untiring services to the medical profession, and particularly to the University, should be lost to the city. Dr. Hawthorne, in reply, referred to the regret with which he left the service of the University and Queen Margaret College, and advocated the equalisation of the conditions of examination in the medical faculty of the two bodies. He paid a warm tribute to the inspiring influence in the school of Professor Gairdner, who had done so much for the advancement of its name and fame. Dr. Hawthorne received a most enthusiastic welcome, and carries with him the warmest good wishes of the profession in Glasgow.

The Disciplinary Powers of the Scottish Universities.

I am glad to note that at a meeting of the Edinburgh University Court on Tuesday last a proposal was under consideration to obtain penal and disciplinary powers over graduates so as to empower a university to remove from its roll of graduates any graduate who may have been found guilty of a criminal offence or other misconduct. The Court while alive to the difficulties of the proposal agreed to confer with other universities on the whole matter and with that view to appoint representatives to a joint committee. This action on the part of the University of Edinburgh is very satisfactory. There had been some reason to think that the University of Edinburgh was behind the other universities in its desire to acquire such powers as are obviously needed in bodies which qualify so large a number of medical practitioners. But its action on Tuesday leads to the hope that this feeling has been changed. Considering its position as a school of medicine and its great influence over the other Scottish Universities, it is gratifying to have to report such a change. It is especially so in view of the near approach of the meeting of the General Medical Council, to which, doubtless, the action of the leading university of Scotland will be duly reported.

Nov. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The University of Dublin.

THE opening meeting of the Dublin University Biological Association will be held in Trinity College on the evening of the 25th inst., when the President, Mr. Robert Woods, will deliver an inaugural address dealing with the subject of "Suppurative Middle-ear Disease and its Relation to the Exanthemata." The speakers will include Dr. Dundas Grant, President of the British Laryngological Association, Dr. Henry Swanzy, Dr. Joseph O'Carroll, and Professor J. Mallett Purser.

The Richmond Asylum.

The medical superintendent of the Richmond District Lunatic Asylum, Mr. Conolly Norman, at the fortnightly meeting of the governors which took place on the 16th inst. reported the death of one male patient from beri-beri and the occurrence of no less than fourteen fresh cases in the female house.

The Jubilee Medal.

Her Majesty has been graciously pleased to confer the Jubilee Commemoration Medal on Surgeon-Major-General A. F. Preston, M.B. Dub., Principal Medical Officer in Ireland.

Municipal Honours to Medical Men.

Sir R. Jackson, C.B, F.R.C.S.I., and Dr. John J. Cranny were elected Commissioners for the Pembroke Township of Dublin on the 15th inst.

The Typhoid Fever Epidemic at Ligoniel.

Thirteen new cases have occurred up to Nov. 9th, which shows a distinct decline in the epidemic. Since Oct. 6th there have been six deaths. The question of the water-supply is a most difficult problem. The Water Commissioners only recently came into possession of the springs supplying the upper portion of Ligoniel (these are the contaminated ones), which before this belonged to the board of guardians, who were the water authority of the district. The Commissioners say that the springs were under the control and in custody of the guardians and the whole surroundings with the possibilities of contamination were fully known to them. They say that no steps were taken to guard against pollution and that the tank containing the water seemed never to have been cleaned out since it was made. The Commissioners cannot, they say, without the fullest investigation and for the strongest reason consent to abandon any of the waters supplying the village. Ligoniel is 600 ft. or 700 ft. above sea level; the Commissioners' filters are only 200 ft. above sea level. Hence it will require from nine to twelve months to provide steam engines, a reservoir, and mains for the purpose of raising filtered water from the filters to Ligoniel. The Commissioners having no means of providing a temporary supply decline to take the responsibility of cutting off the water. They will take any steps possible which the guardians may suggest to remove or remedy the causes of danger, but they throw on the guardians the responsibility of cutting off the water-supply. Last week the Commissioners ran off all the water in the pipes, the fountain, and the reservoir, which they cleaned out. The inhabitants of Ligoniel have wisely been advised under present circumstances to boil all the water used.

Serious Condition of Omagh Asylum.

At the meeting of the governors of the Omagh Asylum held on Nov. 11th, Dr. George P. O'Farrell, Inspector of Lunatics, presented a report, the result of a very careful inspection of the asylum by himself, his colleague, Dr. Courtney, and the consulting architect of the Board of Control. He thinks greater efforts should have been made to remedy defects in connexion with the old system of drainage and sanitary appliances which were to be removed on the completion of the new works. In regard to the percentage of deaths on the average number resident in 1896 it gave a high average for an Irish asylum—viz., 9·8. But this average had been largely exceeded in the current year, as since Jan. 1st last there has been an unusual amount of serious sickness and a heavy mortality. From Jan. 1st until Oct. 1st there had been 388 cases of sickness, with 79 deaths, the majority of which were due to phthisis or other respiratory diseases. Throughout the present year there had been an epidemic presenting in many cases symptoms of typhoid fever but which in the asylum books were described as influenza in accordance with the opinion of the consulting and visiting physician of the institution who stated that in his large practice in the surrounding country he had seen many similar cases which were undoubtedly of an influenza nature. On the male side there had been 83 such cases with 18 deaths, and on the female side 40 with 5 deaths. There were five cases of erysipelas among the patients, and one man was attacked with unmistakeable typhoid fever. Apart from the question of overcrowding and sanitation Dr. O'Farrell reports that the condition of the asylum is not quite satisfactory. There is a relatively large number of excitable patients in certain divisions, and many express frequent complaints of violence or discontent with their treatment. The number of such cases was greater in the Omagh Asylum than in the neighbouring asylums. The changes among the attendants by resignation and dismissal were frequent, and there were numerous charges of intemperance amongst them brought before the board. An institution was improved by raising the knowledge and status of those in immediate and constant charge of the patients. Sufficient attention was not devoted to the recreation of the patients; the food was not satisfactory, and a more liberal and varied dietary might be introduced. Dr. O'Farrell did not blame the management of the institution, which had been thrown into confusion by the structural works in progress. He recommended the formation of a visiting committee to

Digitized by Google

go carefully through the different divisions, and the sick and infirm should be placed in charge of a trained hospital nurse. Mr. Parry, C.E. (Dublin), reported that the existing drainage plans were found by him in many respects to be incomplete and unreliable; the general arrangement of water-closets was imperfect and antiquated, and there was a cesspool which was a source of danger to the inmates. In one of the tanks the water was quite unfit for drinking and it was not a little remarkable that this water supplied the divisions in which by far the largest number of cases occurred, and this water was condemned by the analyst. In another tank the water was in an exceedingly dirty condition. He thought this evidence in regard to the water (bad storage arrangements and uncleanliness of the tanks) appeared to show that they were the most probable and immediate causes of the epidemic of typhoid fever, although the defects in the old drains might be regarded as one of the predisposing factors. The governors, looking on these reports as disclosing such a serious state of affairs, appointed a committee to consider them and they also decided to print and circulate these reports amongst the members of the Board of Control and to consider the recommendations of the committee at the January meeting.

The Belfast Royal Hospital.

At the annual meeting, held on Nov. 15th, it was reported that during the past year (ending Aug. 31st) 2101 new cases were treated in the wards, which with 143 remaining from the previous year made a total of 2244 intern patients. Of these 1279 were surgical and 965 medical. There were 21,819 new extern cases, so that if intern and extern patients be added together there is found in Belfast, a city with a population of 300,000, the large number of 23,920 persons receiving treatment at the Royal Hospital. 138 students attended the hospital during the winter and 98 during the summer session. The receipts from all sources for the year were £7355 11*s.* 4*d*, and the expenditure was £8095 3*s.* 5*d.*, consequently there is a balance against the hospital of £739 12*s.* 1*d.* The year commenced with a debt of £1068 1*s.* 2*d.*, and it ends with a deficit of £349 1*s.* 11*d.* Reference was made at the meeting to the very important and encouraging fact that during the year a sum of upwards of £100,000 has been collected or promised for a building on a new site, a fact which shows plainly that the claims of the hospital were never more fully recognised by the public than at present.

Medical Candidates for the City Council.

The municipal elections consequent on the enlarged area of the City of Belfast are now in full progress, and amongst the candidates for the posts of aldermen and councillors are eleven members of the medical profession.

Nov. 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Over-Expenditure in Hospitals.

DR. NAVAARE has presented to the Municipal Council a report upon the financial statement of the Assistance Publique for the year 1895. The increase in expenses had appeared to the council so extraordinary that further inquiry was necessary. The total sum spent by the Assistance Publique was 36,600,856 francs, being 441,242 francs in excess of the sum spent in 1894. One of the most extraordinary items in the expenditure is the sum set down for milk, and one can only wonder where all the milk has gone to, seeing that there has been no proportionate diminution in the consumption of wine and beer. Dr. Navarre attributes this state of affairs to gross negligence in the administrators of hospitals, who have exercised no proper control over the resident staffs, &c. At Bicêtre it appears that 100 litres of milk have been used in the preparation of *bœuf à la mode* and 27 litres in the due cooking of some rabbits, while several patients were entered as the recipients of milk which they were not getting. During 1895 the price of charcoal dropped, but under the item of *chauffage* 150,514 francs have been expended, or 80 francs in excess of what was spent the previous year. The sums spent upon instruments and hospital fittings have been enormous, and designed, it is suggested, to attract wealthy patients and not to minister to the poor. From Cochin a requisition was made at the Central Pharmacy for 20,000 metres of silk ligature and 10,000 metres of catgut. This fantastic demand represented only the needs of three months and at the time it was made the hospital was in possession of 1800 metres of silk ligature sterilised and 8000 metres unprepared and 800 metres of catgut ligature sterilised and 1000 metres unprepared. A very good case for an investigation would seem to have been made out.

The Bacteriology of Acute Articular Rheumatism.

M. Thiroloix reports that since March last year he has found five times in the blood of persons suffering from acute muscular rheumatism the pathogenic bacillus. The bacillus appears in the first culture at variable intervals. Upon each occasion when he has made intravenous injections he has obtained cardiac and pleuro-pulmonary lesions as well as articular troubles, which have only made their appearance after the symptoms of affected heart. He gives it as his opinion, therefore, that cardiac lesions precede articular lesions or exist without them.

The Return of M. Raoul's Expedition in Malaita.

On Monday last M. Raoul, Pharmacien-en-Chef des Colonies, accompanied by M. Mary, Pharmacien-principal, arrived in the *Laos*. M. Raoul had been engaged upon a Government mission to make researches in Malaita into the indigenous plants with a view of seeing if any existed that might be turned to account scientifically or commercially. A number of natives took part in the expedition and several of M. Raoul's party were bitten by snakes of different sorts. They are stated to owe their lives to injections of Dr. Calmette's serum with which the expedition was amply provided.

An Accusation against a Graduate of the Faculty of Medicine.

For some days past a serious charge has been hanging over the head of M. Heim, a young graduate in Natural History. The newly-appointed professor in this subject, Professor Blanchard, upon taking up his department and the laboratory connected, asked M. Heim to make an inventory of the various specimens and apparatus belonging to this laboratory of which M. Heim had been in charge pending the election of the new professor. M. Heim, who was travelling, asked that the taking of the inventory might be put off, and when he returned, as he was then taking his holiday away from Paris, asked for a still further delay. As upon being asked a third time M. Heim still did not appear Professor Blanchard proceeded to make the inventory. He found in a box with M. Heim's name upon it various instruments and specimens labeled as M. Heim's personal property which belonged to the Natural History Museum of the Physiological Laboratory at the Faculty of Medicine and to sundry other laboratories where M. Heim had worked, objects which had been given up for lost though much sought after. Professor Blanchard accordingly drew up a report against M. Heim, and the latter, when at last he did come back, protested vehemently against the breaking open of his chest in his absence and further affirmed that he had no intention of appropriating these instruments of which he had made legal use in his researches before he went away and that he had put them all away in a hurry before his departure, putting them all together that he might know where to find them when he came back. The Rector of the Academy of Paris, M. Gréard, took the advice of the University which had already nominated a disciplinary committee according to its own laws and regulations. So the matter has been submitted to this committee for inquiry. Some doubt arose as to whether the University had power to take up a case of this sort but it was finally decided, upon a careful report drawn up by Professor Glasson of the Faculty of Law, that it had power. When all the formalities have been complied with the inquiry will proceed as rapidly as possible for a matter of this kind needs to be settled one way or the other as soon as possible. It is hardly likely, however, that a decision will be given before the end of the week. The Commission sat for the first time on Friday, Nov. 12th, to hear the reading of the report of Professor Blanchard. M. Heim appeared before it on Saturday, and on Monday the hearing of the witnesses, who are thirty-two in number, was commenced.

The late Dr. T. W. Evans.

Dr. Thomas William Evans, the well-known American dentist, died on Nov. 14th at his house in the Avenue du

Digitized by Google

Bois de Boulogne. When the Empress Eugénie quitted the Tuileries on Sept. 4th, 1870, she went in a cab to his house where she stayed the night and next day he travelled with her in a carriage to the coast. She then succeeded in escaping from France in a small vessel which landed her at Ryde. Dr. Evans's practice was very select and several crowned heads availed themselves of his skill. He was the proprietor of the *American Register*.

Nov. 16th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Virchow's Jubilee.

THE fiftieth anniversary of Professor Virchow's joining the teaching staff of the Berlin University was celebrated on Nov. 6th. In 1847 Professor Virchow, who had previously belonged to the Army Medical Staff, was appointed a *privat-docent* at the University, but political considerations were all-powerful after the revolutionary troubles of 1848, and as he was known to hold democratic opinions he was under the necessity of leaving Berlin and accepting a professorship at Würzburg, in Bavaria. His exile, however, did not last very long, for as far back as 1856 he was elected Ordinary Professor of Pathological Anatomy in Berlin, an appointment which he still retains. On account of Professor Virchow's infirm state of health the jubilee proceedings were of a more private character than would have otherwise been the case, being limited to addresses of congratulation delivered by the rector of the University and the dean and professor of the medical faculty. The rector, Professor Schmoller, referred to Professor Virchow's achievements not only as a physician and a pathologist, but also as a biologist and as a savant whose methods of research had influenced every branch of human knowledge. The dean, Professor Heubner, eulogised him as a *privat-docent* of an altogether superior order—a teacher not only of students but also of professors. At an age when young men were, as a rule, far from having mastered what had been already discovered he had succeeded in solving the most difficult problems of biology. Professor Virchow in his reply pointed out that he was happy in the knowledge that a body of men now existed in German universities strong enough not only to maintain the principles laid down by him but also to continue the work in the light of modern developments. He felt that his work was done and that he was now entitled to retire from his academical position, especially after having succeeded in obtaining a promise from the Government that a new and modern pathological institute and museum would be constructed after his designs. A great number of telegrams, letters, and other marks of Professor Virchow's great popularity were received by him during the day.

The Training of Nurses and the Removal of Hospital Patients in London.

In the "Verein für Innere Medicin," a paper has been read by Dr. George Meyer on the Medical Institutions of London. The author, who had spent several weeks in the English metropolis at the time of Queen Victoria's Diamond Jubilee, first mentioned the display of nursing appliances in connexion with the Victorian Era Exhibition at Earls Court, which, he said, offered an opportunity of realising the high standard of nursing in England. In his opinion nurses were very well trained in England, the length of service required from probationers enabling them to get a more perfect knowledge of their duties than in other countries. He gave particulars of the different training schools, spoke of hospital nurses, private nurses, and district nurses, and showed specimens of the rules and regulations of several nursing institutions. He then passed on to the First Aid and ambulance arrangements made by the St. John Ambulance Association, which he had seen at work on the occasion of the Jubilee procession. The principal feature of Dr. Meyer's paper was an account of the mode of removing infectious cases. He had for a long time urged the necessity of reform in the ambulance arrangements in Berlin, and he now described the ambulance vehicles belonging to the different London hospitals and showed photographs of some of them. He also described the mode of notification of infectious disease and the duties of the medical officers of health in connexion with the disinfection of dwellings. He specially commended the mode of conveying patients to hospital and the consideration with which their friends were informed both of their condition and of the appearance of dangerous symptoms; the printed forms used for this purpose were also shown to the society. Dr. Meyer concluded his remarks by expressing his thanks to the hospital managers, and to the medical officers who had kindly assisted him in his inquiries.

Dr. Calot's Treatment of Spondylitis.

Dr. Calot's method of treating spondylitis by "brisement forcé" of the vertebral column has been tried by some German surgeons and orthopædists, and in the *Deutsche Medicinische Wochenschrift* Professor Lorenz, of Vienna, discusses the subject from a theoretical point of view. He says that the risks of this method are very great, for not only may the spinal cord be injured, but prævertebral abscesses may burst and discharge their tuberculous contents into the surrounding tissues. But even if these apprehensions are unfounded (as they are, in fact, in Dr. Calot's opinion) the success of the treatment must obviously depend upon the regenerative power of the broken vertebra. The question is whether this power is strong enough to form so much new osseous substance that the cavity in the vertebra produced by the tuberculous process may be filled up for without a sufficient formation of new osseous substance a relapse must of course occur sooner or later. Professor Lorenz therefore warns patients and medical men not to entertain too great expectations, especially as little more than a year has elapsed since Dr. Calot began his treatment, and this time is too short for the formation of a decided opinion. The procedure described by Dr. Calot consists in forced traction of the vertebral column by two assistants who seize both ends of the trunk whilst the surgeon himself produces a "brisement" of the deformity by making firm pressure on the prominent point of the vertebral column. This procedure is rather rough, and will undoubtedly be replaced by the use of instruments which will allow the force exerted in traction and pressure to be graduated according to the individual case. Professor Lorenz has hitherto treated only one case after the new method, the patient being a boy, ten years of age, who had suffered from spondylitis for three years. A year ago a slight paresis of both legs developed, sensibility and the control of the bladder and rectum remaining normal. There was no pain and the boy's general state was comparatively good. The "redressement" was performed strictly in accordance with Dr. Calot's directions, chloroform being administered during the operation. Professor Lorenz found it easy to straighten the curvature and to apply the plaster bandage; but when the patient recovered from the anæsthesia there was total paralysis of the lower extremities, together with anuria and paralysis of the rectum. Control of the bowels and bladder was regained after a fortnight, but the paraplegia still persists. The plaster bandage was, of course, at once removed, and the curvature is now, two months after the operation, nearly the same as before. Professor Lorenz is far from judging the method by the result of only one case, but obviously the operation is not so harmless as its author alleges.—The same subject was recently discussed at a meeting of the Medical Society of Hamburg. Professor Krause mentioned that Dr. Calot in thirty-seven cases had only once observed a slight paresis following the operation, and he suggested some modifications of the plaster bandage, by which it might be made less irksome to the patient. He allows patients to leave their beds very soon, a matter which is very important for their general health. Two cases were shown. One of these patients was a girl, six years of age, with lumbar spondylitis and a chronic pelvic abscess on the left side. The abscess was treated by puncture and injections of iodoform. The "redressement" required fifty minutes, considerable force being necessary to overcome the deformity, and the application of the bandage occupied nearly the same time. The patient could leave her bed after three days. The other patient was a boy, aged ten years, and the operation was finished in twenty minutes. Both patients were shown to the society and were able to walk freely with the bandage. In the discussion Dr. Kümmel stated that one of his cases, a child, was insensible for three days after the operation, but eventually recovered and now felt quite well. He proposed the adjournment of the discussion for a few months till more ample experience should be accumulated.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Italian Commission on the Pestis Bubonica (concluded).

PROFESSOR LUSTIG and his colleagues arrived in Bombay on June 12th to find an exacerbation of the epidemic owing to the monsoon and torrential rains, and, loyally aided by the British authorities, they lost no time in utilising their opportunities. Besides attending assiduously at the hospitals they put their services to the test at the Veterinary College, and the experiments conducted there by Dr. Galeotti and Dr. Malenchini yielded satisfactory results. "Only the apes not treated with the serum died after three or four days from the plague," according to Professor Lustig. The distrust of serotherapy on the part of the natives, both professional and lay, restricted its application only to typical cases in the foci of recent infection and in those forms held by the local physicians to be especially grave; and here, again, Professor Lustig claims to have "scored a distinct success." The effects of the serum, he says, revealed themselves after six hours; the high fever subsided, the "smania" (excessive agitation of the body) ceased, the delirium disappeared, and a general improvement set in. "The bubbone" after the second or third injection gave no more pain, a condition of "benessere" (well-being) ensued, and convalescence was less protracted and debilitating than in the cases, not frequent, in which the patient made a natural recovery. Out of thirty typical cases of the pestis bubonica subjected to his serum treatment, only four, says Professor Lustig, died. The serum, moreover, produced of itself no malady whatever. It is, he admits, inefficacious when the bacilli of the pestis have in millions penetrated the torrent of the circulation—this latter taking place between the fifth and seventh day of the disease. So much for the cure. As to the prophylaxis, "the preservative vaccinations," he says, "could not be executed in a crucial manner in a country like India, with a population rootedly prejudiced against it; and from operations among persons like Europeans, Neo-Christians, and Parsees, who are much less liable to the pestis than the Hindoos, no certain or decisive data could be obtained. And even when numerous vaccinations were affected, how could we know whether they had been efficacious or for how long a time? ..... I thought that if we wanted to assure ourselves of the efficacy of our preventive vaccine and to bring it home to the mind of others we ought to try it on man in such circumstances only as admitted of our 'vaccinating' all the individuals who were in contact, direct or indirect, with the plague-stricken in the most virulent period of the infection. This opportunity I had at Poona, where the pestis having broken out in a native regiment, they were all, together with their families, isolated in a place of observation. But of this opportunity I could not avail myself because the military authorities did not think it prudent to oblige, contrary to custom, Hindoos and Mahometans to undergo operations which excited their misgiving and discontent. The biological affinities between the ape and man and the identity of the *forma morbosa* between them counselled our resolving the problem of immunisation by utilising apes. My two colleagues, Dr. Galeotti and Dr. Malenchini, to whom the experiments were entrusted, with the help of the assistants of the British School, succeeded in demonstrating that our vaccinal practice preserves those animals in an absolute manner from the pestis even when most virulent, while the same apes concurrently infected with the same quantity of pestiferous matter and through the same channels, but not vaccinated, died without exception. How long," continues Professor Lustig, "does the immunity remain effective? Certainly a month. Whether longer, and how much longer, our experiments now proceeding will determine. Having demonstrated," he adds, "the curative efficacy, even in man, of the serum prepared by us we would gladly have extended the use of it on a larger scale; but for us life in India was costly, as also was the preparation of the serum, and our sojourn had to close in two months. The object of our mission was, however, attained." Professor Lustig concludes his report by illustrating the uphill fight maintained by medical science in India against native obstruction. England has to combat self-styled "reformers" who ostensibly adopt her innovations but secretly neutralise them, using for their purpose the immense leverage provided them by religious superstition. This vindication of our efforts by Professor Lustig will be read with interest at a time when representatives of other continental powers are the reverse of charitable in criticising our methods.

Nov. 14th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board under the "Four Years Regulations":—

Materia Medica:

Beasley, Ernest Cecil Watkins.
Braidwood, Thomas Lithgow.
Claridge, William Walton.
Courtenay, Frederick William Edward.
Hughes, John Worthington.
Jones, Thomas.
McCarthy, Thomas.
Morris, Richard Clayton.
Williams, Penry Garnons.

The following gentlemen passed the necessary examination of the Board in the subjects indicated under the "Five Years Regulations":—

Part I., Chemistry and Physics:—

Ashton, John Hilton.
Bent, Sidney Charles Henry.
Bradley, Charles Reginald.
Browne, William Walker.
Butcher, Harry Hendy.
Cauper, James.
Cowper, Claude Marriott Lovell.
Crofts, Arthur Douglas.
Dix, Charles.
Elwood, William Henry.
Ferguson, Lionel Cecil.
Goldie, Walter Leigh Mackinnon.
Harvey, Arthur George.
Higgins, James Gilkinson.
Hollist, Gerald Wethereli Capron.
Ide, Harry.
Jacques, Harold.
Keir, John Duncan.
Latham, Thomas Jones.
Lawry, Richard Coger.
Lemon, Charles John.
Margetts, Horace Palmer.
Martin, William.
Mummery, Norman Howard.
Murdoch, Horace Thomas Thorne.
Oades, Geoffry Smith.
Paget, Walter Gray.
Pallant, Santiago Luis.
Paterson, Edward Haldane.
Poyser, Richard Cruikshank.
Smith, Frank Wybourn.
Spalding, Archibald Denize.
Van Dyk, Adriaan Francois.
Waddell, Hugh.
Wallis, Harold Wishaw.
Wilmot, Reginald Cameron.

Part II., Practical Pharmacy:

Baker, Dodington George Richard Sherston.
Bannerman, Charles Harold.
Barnes, George.
Blake, Percy Ryall.
Boyle, Henry Edmond Gaskin.
Butler, Archibald.
Cheese, Frederick William.
Clark, John Wilders Hambly.
Crowther, Sydney Nelson.
Ekins, Charles Maxwell.
Elworthy, Henry Herbert.
Evans, Edward.
Gauld, Reginald.
Griffith, Idwal.
Grimwade, Alfred Sheppard.
Harris, Henry Arthur Clifton.
Higgins, Alexander George.
Hobbs, Albert Remington.
Hope-Simpson, Adam Pearson.
Hutchinson, George Arnold.
Kennard, Douglas Frederick.
Latham, Godfrey Holland.
Nourse, Arthur William.
Pinker, Henry George.
Randolph, William Henry.
Roche, Nelson Joseph.
Ross, Hugh Campbell.
Samuel, David.
Smith, Francis Maylett.
Soper, George Bertram Spencer.
Stolterfoth, Charles Sigismund.
Thompson, Reginald.
Turtle, Godfrey de Bec.
Vores, Cyril Preston.
Wells, John.
Wood, Frederick Joseph.

Part III., Elementary Biology:

Arnould, Loris Arthur.
Beadel, Algernon James.
Crampton, Walter.
Fullagar, Walter Swainson.
Hughes, Geoffrey Wallace Grainger.
James, Reginald Valpy.
Jones, Alfred Lancelot.
Keed, Charles Russell.
McCowen, William Terrance.
Oakeley, Arthur Eckley.
Paterson, Edward Haldane.
Sansom, Bertram Eli.
Snell, John Percy Brooking.
Tatchell, William Arthur.
Thornton, Edward Newbury.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following are the arrangements for the Final Examination for the Fellowship, for which forty-five candidates have entered their names, viz.:—

Monday, Nov. 22nd.—Written Examination, 1.30 to 5.30 at Examination Hall.

Tuesday, Nov. 23rd.—Clinical Examination, 2.30 to about 5.30 P.M. at Examination Hall.

Wednesday, Nov. 24th.—Operations, 1.30 to about 6 P.M. at Examination Hall.

Thursday, Nov. 25th.—Surgical Anatomy, 2 to 4.15 p.m. at Examination Hall.

Friday, Nov. 26th.—Pathology, 5 to 7.30 P.M. at Royal College of Surgeons.

Saturday, Nov. 27th.—Pathology, 5 to 7 P.M. at Royal College of Surgeons.

All candidates will be required to attend on Monday, Tuesday, Wednesday, and Thursday, and on Friday or Saturday.

FOREIGN UNIVERSITY INTELLIGENCE. — *Berlin:* Dr. Hermann Munk, Extraordinary Professor of Physiology, has been promoted to the rank of Honorary Ordinary Professor.—*Cracow:* Dr. Léon Wachholz, Extraordinary Professor of Forensic Medicine, has been promoted to an

Digitized by Google

Ordinary Professorship.—*Gratz:* Dr. Alfred Kossler has been recognised as *privat-docent* of Internal Medicine.—*Lemberg:* Dr. Oscar Widmann has been recognised as *privat-docent* of Internal Medicine, and Dr. Gustav Piotrowski as *privat-docent* of Physiology.—*Prague (Bohemian University):* Dr. Wenzel Rubeska, *privat-docent* of Midwifery and Gynæcology, has been promoted to an Extraordinary Professorship.—*Utrecht:* Dr. H. Zwaardemaker has been appointed Professor of Physiology in succession to Dr. Engelmann.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—An examination for the certificates in psychological medicine issued by this association will be held in London, Edinburgh, Glasgow, Aberdeen, and Dublin in December. The exact date has not yet been fixed, but will be duly notified in our columns. At least fourteen days' notice must be given by intending candidates to Dr. Spence, Burntwood Asylum, Lichfield, who is the registrar of the association.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—An emergency meeting of the Rahere Lodge, No. 2546, was held at Frascati's Restaurant on the evening of Nov. 9th, Bro. W. J. Walsham, W.M., being in the chair. Messrs. Cripps Lawrence, John Adams, Trechmann, and Westbrook were initiated into Freemasonry by Bro. Godson. Bro. Surgeon-Major J. G. Harwood, M.S., and Bro. Dr. M. A. Haviland, of Penang, Straits Settlements, were elected joining members. Bros. McLean, Haines, Sargant, Matthews, and Shewell were admitted to the third degree by the W.M. Thirty-four members with their guests afterwards dined together.

LITERARY INTELLIGENCE.—Commencing with the New Year, Messrs. John Wright and Co., Bristol, will be the European publishers of *The Laryngoscope*, a monthly journal of sixty-four pages devoted to diseases of the nose, throat, and ear. It is the official organ of the New York Academy of Medicine, laryngological section; the American Laryngological, Rhinological and Otological Society, southern section; and the Western Otological, Laryngological and Rhinological Association. In the new volume it is intended that the British contributions shall form a more prominent feature than heretofore. The price is 1*s.* per month, or 10*s.* per annum, post free.—The Rebman Publishing Company have ready for early publication a small book by Mr. D'Arcy Power entitled "Some Points in the Anatomy, Pathology, and Surgery of Intussusception," being the Hunterian Lectures for 1897 delivered at the Royal College of Surgeons. They will also issue next week Dr. Alexander Morison's new book on "Cardiac Failure and its Treatment, with especial reference to Baths and Exercises," which has been unavoidably delayed in the press.

PRESENTATIONS TO MEDICAL MEN.—In the medical officer's room at the Plymouth municipal buildings, on Oct. 29th, Mr. F. M. Williams, L.R.C.P. Edin., M.R.C.S. Eng., D.P.H. (the medical officer of health), in the presence of the staff of the Sanitary Committee, presented Mr. J. H. S. May, M.R.C.S. Eng., L.S.A., J.P., who has been for several years chairman of the Sanitary Committee, with an illuminated address and a silver bowl bearing the following inscription: "Presented to J. H. S. May, Esq., J.P., by the staff of the Sanitary Committee on his retirement from the Plymouth County Council, October 31st, 1897."—Mr. James Fletcher, M.B., C.M., D.P.H. Aberd., has been presented with a silver-mounted dressing-bag by the members of the nursing and working staff of the City Hospital, Aberdeen, as a mark of their appreciation of his services for two years as resident physician and lecturer.—A complimentary dinner was given at Weston-super-Mare on Oct. 27th to Mr. G. B. Fraser, M.R.C.S. Eng., L.S.A., who is relinquishing the captaincy of the volunteer fire brigade after having held the appointment for a considerable period. During the evening Mr. Fraser was presented with a pair of silver candlesticks.—At a meeting on the 5th instant of the Dunston Colliery Ambulance Classes in the board schools, Dunston, for the purpose of presenting the successful candidates with medallions or certificates, Mr. A. A. Abraham, L.R.C.S. Irel., of Gateshead, was the recipient of a meerschaum pipe from the members of the classes.—At the Conservative Club, in Cardiff, on the 9th inst., a presentation was made to Mr. Edward Treharne, L.R.C.P. and S. Edin., J.P., in recognition of his services as chairman of the Cardiff Conservative Association for eight years, from 1889 to 1897. The presentation consisted of three silver fruit and flower bowls, candle-sticks, and a pair of entrée dishes.

HENSHAW'S BLIND ASYLUM.—Some changes are proposed in the scope and management of this old and important institution for the blind. At the quarterly meeting of the trustees and board of governors held on the 3rd inst. it was mentioned that there were now 202 inmates, the largest number ever reached, and the asylum "was taxed to its utmost capacity in housing and instructing them." Of these 92 were children. The board considered it of the utmost importance to admit children to be educated and all applications for them had been granted. Men are kept in the asylum for a few years only until they have learned a trade when they go out and earn their own living. The benefits of the asylum are not confined to Manchester, for of seven applicants elected at the meeting two were from Macclesfield. All these were children, the eldest not being more than sixteen. The board considered several additions and alterations in the scheme of the charity for which it was decided to ask the sanction of the Charity Commissioners. One was that the age for admission "be not less than five years instead of nine." Another was that the board of governors should have power to grant pensions or subsidies to blind persons. It was pointed out that this was done in Yorkshire institutions, in York, Leeds, and Bradford, and the pensions granted were received by about 2000 persons. This has, indeed, virtually been done at the Old Trafford institution, and the board "were now going to the Charity Commissioners to legalise what they had been doing and ask at the same time for some scheme more comprehensive and elastic" than the present one. We may hope that their beneficent illegality will be pardoned. Cases occur where persons become blind in following their avocations and if they wished to live with their friends it would be a hardship for them to be kept in the asylum. It appears, also, that elderly people can be boarded out for less than they cost in the institution and the space gained by the removal of the old people can be utilised for children for educational purposes. The pensions and subsidies are frequently before the board for supervision and can be cancelled or continued at discretion. The meeting also approved of an application for investing the board of governors with "power to purchase land or buildings for the extension or development of the objects of the charity."

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.—At a meeting of this society held on Oct. 29th Dr. Dundas Grant, the President, showed three cases of Frontal Headache of Nasal Origin. The first was dependent on frontal sinus disease. The patient was a man, aged twenty-eight years, who complained of left frontal headache and discharge from the left nostril. Exploration of the maxillary antrum yielding a negative result the anterior part of the middle turbinal was removed, a Hartman's tube was introduced into the frontal sinus through the natural orifice, and a 1 per cent. solution of menthol was injected by means of a syringe. The headache had diminished but not yet disappeared. The second case was dependent on sphenoidal sinus disease. The patient was a woman aged twenty-nine years. A slight degree of relief was obtained by an incomplete removal of polypoid outgrowths from the middle turbinal. Complete relief had been obtained on a later occasion, when during syringing a mass of polypoid growth detached itself from the interior of the nose and was found to be growing from a plate of bone which came away with it. A large opening was then found leading into the sphenoidal sinus and the plate of bone was obviously the anterior wall of this cavity. The third case was due to suppuration in the antrum of Highmore. The patient was a woman aged fifty-one years. Mr. Lennox Browne and Mr. Marsh made some remarks on these cases.—Mr. Wyatt Wingrave showed a case of Aphonia with Paralysis of the Tensors of the Vocal Cords in a man, aged twenty-five years, who suffered from sudden loss of voice for four weeks and huskiness for twelve months, with slight cough, but no expectoration; in other respects he expressed himself as being in perfect health. Laryngoscopic examination showed slight peri-arytenoid swelling extending to the ventricular bands. The interrupted current with vocal drill quickly restored the voice, which was now strong but deep in tone and somewhat uncertain. Mr. Bark, Dr. Whistler, and others took part in the discussion.—The Presidential address on Some Lines of Progress in Laryngology, Rhinology, and Otology was delivered by Dr. Dundas Grant, who then showed a series of four cases of mastoid operation.—Mr. Wyatt Wingrave showed a case of Tuberculous Disease of the Middle-ear complicated by Optic Neuritis

Digitized by Google

occurring in a woman, aged twenty-five years, who had suffered from a painless discharge with deafness from both ears since infancy, and whose family history was strongly tuberculous. On Aug. 30th last she noticed dimness of vision in the right eye, and in three days became totally blind in that eye.

SUPERANNUATION OF A MEDICAL OFFICER.—At the meeting of the Bath Board of Guardians held on Nov. 3rd it was decided to grant a superannuation allowance of £36 per annum to Mr. Frederick W. Hanham, L.R.C.P. Edin., L.F.P.S. Glasg., who has just resigned the post of medical officer to the fourth district of the Bath Union, after having held the appointment for twenty-seven years.

MUNICIPAL MATTERS IN BRISTOL.—At the meeting of the enlarged Bristol Town Council, held on Nov. 9th, Mr. F. Richardson Cross, M.B. Lond., F.R.C.S. Eng., whose nomination we have already announced was unanimously elected High Sheriff; Mr. J. Hancocke Wathen, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A., was elected an Alderman of the city; and Mr. Colston Wintle, L.R.C.P. Lond., M.R.C.S. Eng., was appointed on the new Health Committee of the council.

UNIVERSITY OF CAMBRIDGE.—At the Congregation on Nov. 11th, when the Archbishop of Canterbury and the Lord Chief Justice were admitted to honorary degrees, the following medical degrees were conferred:—Doctor of Medicine: G. J. K. Martyn, B.A., and J. R. Carver, M.A. Bachelor of Medicine and Bachelor of Surgery: A. E Porter, B A.—By the will of the late Dr. Joseph Gedge, who died in 1870 while with Sir Samuel Baker at Khartoum, a sum of £1000 has at length come to the University for the establishment of a biennial prize for original research in physiology, open to graduates of the University.—Mr. Hubert Higgins, B.A., M.R.C.S. Eng., L.R.C.P. Lond., one of the demonstrators of human anatomy in the University Medical School, was on Tuesday elected assistant-surgeon to Addenbrooke's Hospital in the room of Mr. Douty, resigned.

DIPHTHERIA IN LONDON.—During the week ended Nov. 6th there were registered 59 deaths from diphtheria in the county of London, against 45, 55, and 65 in the three preceding weeks. The 59 deaths were 11 in excess of the average of the corresponding weeks of the decennium 1887-96, and with one exception were of persons under twenty years of age. Between the ages of one and five years 37 deaths occurred. Seven deaths were of persons residing in Battersea; Mile End Old Town and Poplar were each credited with 5 deaths; St. Pancras and Newington each with 4; and Hackney, Lambeth, and Camberwell sanitary areas each with 3 deaths. There were 1056 cases of diphtheria in hospital at the close of the week, and 164 fresh admissions during the week. In the outer ring there were 17 deaths registered from diphtheria, of which 6 occurred in West Ham and 4 in Dartford registration districts. In the week ended Nov. 13th the registered deaths from diphtheria in London further fell to 46, the corrected decennial average being 51. Five deaths belonged to Poplar; Kensington, St. Pancras, Camberwell, and Wandsworth were each credited with 4 deaths; and Fulham, Clerkenwell, and Battersea sanitary areas each with 3 deaths. All the 46 deaths were of persons aged under twenty years, and 28 occurred in children aged from one to five years. The admissions to hospital during the week numbered 149, and 1066 persons remained under treatment at the close of the week. In the outer ring the registered deaths rose to 26, of which 10 occurred in Edmonton, 4 in Dartford, 3 in Hendon, and 3 in West Ham registration districts.

BUTLER, C., M.D. Brux., M.R.C.S., L.R.C.P., has been appointed Anæsthetist to the Samaritan Free Hospital for Women and Children, Marylebone-road, London.

BYERS, W. GORDON M., M.D., C.M., has been appointed Junior House Surgeon to the Royal London Ophthalmic Hospital, Moorfields, E.C.

CAIRNS, W. M., M.B., C.M. Edin., has been appointed an Honorary District Medical Officer to the Ladies' Charity and Lying-in Hospital, Brownlow Hill, Liverpool.

CALDERWOOD, GEORGE, M.D. Glasg., has been re-appointed Medical Officer of Health by the Egremont Urban District Council.

CONDON, F. W., F.R.C.S. Irel., has been appointed a Visiting Surgeon to the Sheil Hospital, Ballyshannon.

CRRIGHTON, R. H., B.A., M.B., M.A.O.R.U.I., has been appointed a Visiting Surgeon to the Sheil Hospital, Ballyshannon.

CROWTHER, THOS., M.D. Aberd., M.R.C.S., has been re-appointed Medical Officer of Health by the Midgley Urban District Council.

DARBY, H. C., L.R.C.P., L.R.C.S. Edin., has been appointed a Medical Officer by the Lye Urban District Council.

DIXON, T., M.B., B.S. Durh., has been appointed Medical Officer of Health by the Barndon Urban District Council.

DONALD, HUGH CALLIGAN, M.B., C.M., F.R.C.S. Edin., has been appointed Acting Surgeon to the Infirmary, Paisley.

FALLOWS, J., L.R.C.S. Edin., has been re-appointed House Surgeon to the Royal Ear Hospital, Soho, London.

GLASSON, C. J., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer by the Joint Committee of the Ellesmere Urban and Rural District Councils.

HOPE, GEO., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Medical Officer of Health for the Greenford Urban Sanitary District.

KELLY, DANIEL, L.R.C.S. Irel., L.R.C.S. Edin., has been appointed a Resident Medical Officer to the Sheil Hospital, Ballyshannon.

KNAPP, E. M. M., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Hereford District Council.

LATHAM, ARTHUR, M.A., M.B., B.Ch. Oxon., M.A. Cantab., has been appointed Assistant Physician to the Victoria Hospital for Sick Children, Chelsea.

LATTER, CECIL, M.D., B.C., B.A. Cantab., has been appointed Honorary Medical Officer to the St. Andrew's Convalescent Home, Folkestone.

LITTLE, JAMES, M.D. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the Maryport Urban District Council.

MACLENNAN, D. N., M.D. Canada, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Royal London Ophthalmic Hospital, Moorfields, E.C.

MACLEOD, HAROLD H. B., F.R.C.S. Edin., L.R.C.P. Lond., has been appointed Surgeon to the Salop Infirmary, vice William Eddowes.

MORETON, REGINALD, L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer to the Chester Infirmary.

MORGAN, A. LUCAS, L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Medical Officer for Out-door Patients to the Swansea General and Eye Hospital, vice J. S. H. Roberts.

PATON, J. H. P., M.B., C.M. Edin., has been appointed a Medical Officer to the Ayr County Hospital.

PEARCE, ARTHUR, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for the Salcombe (Devonshire) Urban District.

PEARCE, J. P., M.R.C.S., has been re-appointed Medical Officer of Health for Lewes.

PITT, C. WIGHTWICK, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for Malmesbury.

POOLE, C. C., M.R.C.S. & L.S.A. Lond., has been appointed Resident Medical Officer of the General Dispensary and Infirmary, Pontefract.

ROBERTS, J. S. H., L.R.C.P. Lond., M.R.C.S., has been appointed a Physician to the Swansea General and Eye Hospital vice J. A. Rawlings.

ROBINSON, C. A., B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the Royal Portsmouth Hospital, vice W. H. Farmer.

SEARLE, G. P., has been appointed a House Surgeon to the Wrexham Infirmary, vice C. E. Salt, resigned.

SHEPERD, R. J., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer of Health by the Hay Urban District Council.

SILVESTER, W. G., L.R.C.S., L.R.C.P. Edin., has been appointed an Assistant House Surgeon to the Sussex County Hospital, Brighton.

STIRK, P. H., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon to the Exeter Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRADFORD ROYAL INFIRMARY.—Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.

CARDIFF INFIRMARY.—Assistant House Surgeon for six months. Board, washing, and apartments provided.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar for one year. Honorarium 20 guineas.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Assistant House Surgeon for six months. Board, residence, and washing provided, and an honorarium of £10 given conditionally.

DURHAM COUNTY ASYLUM.—Third Assistant Medical Officer. Salary to commence at £100 per annum, with board, lodging, &c. Applications to Dr. Smith, Superintendent, Winterton, Ferryhill.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—House Physician for six months. Board, residence, &c., provided, and an honorarium of £15 15s. given conditionally.

HUDDERSFIELD INFIRMARY.—Junior Assistant House Surgeon. Salary £40 per annum, with board, lodging, and washing.

NORTH EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch.—House Physician for six months. Salary at the rate of £80 per annum. Applications to the Secretary, City Office, 27, Clement's-lane, Lombard-street, E.C.

OWENS COLLEGE, Manchester.—Junior Demonstrator in Anatomy Salary £100, rising by yearly increments to £150.

PARISH OF LAMBETH.—Assistant Medical Officer and Dispenser for the Workhouse, Renfrew-road, Lower Kennington. Salary £100 per year, rising after two years' service to a maximum of £125 per year, with board, apartments, and washing, subject to statutory deductions. Applications to the Clerk, Guardians' Board Room and Offices, Brook-street, Kennington-road, S.E.

PARISH OF ROUSAY AND OGILSHAY, Orkney.—Resident Medical Officer. Salary £51 sterling per annum. Apply to the Clerk of the Parish Council, Rousay, Orkney.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, London.—Assistant Resident Medical Officer for four months. Salary at the rate of £50 per annum, with board, residence, and washing.

ROYAL BERKS HOSPITAL, Reading.—House Physician for six months. Salary £60 per annum, with board, lodging, and washing. Also Assistant Medical Officer for six months. Board, lodging, and washing provided, and an honorarium of 10 guineas given conditionally.

ROYAL EAR HOSPITAL, Frith-street, Soho-square, London.—Assistant Surgeon.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields, E.C.—Non-resident Assistant House Surgeon to Out-patient Department. Salary £15 a year. Also Secretary. Salary £250 per annum.

ROYAL VICTORIA HOSPITAL, Bournemouth.—Ophthalmic Surgeon.

ST. GEORGE'S UNION, London.—Medical Officer for the Workhouse in Wallis-yard, Buckingham Palace-road, S.W., and for the No. 4 Medical Relief District of the Union. Salary as Medical Officer of the Workhouse, £50 per annum, and for the No. 4 District £150 per annum, with such extra medical fees as allowed by the Local Government Board, subject to statutory deductions. Applications to the Clerk, Clerk's Offices, St. George's Vestry Hall, Mount-street, W.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Honorary Physician.

TUNBRIDGE WELLS EYE AND EAR HOSPITAL.—Lady House Surgeon for twelve months. Salary £60, with board, lodging, and washing.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—Assistant Physician to the Out-patients, for three years. Also Physician to the In-patients.

UNIVERSITY COLLEGE, Liverpool.—Senior Demonstrator of Physiology. Salary £125.

WALLASEY DISPENSARY.—House Surgeon, unmarried. Applications to Mr. Wm. Heap, Mim Mount, Penkett-road, Liscard, Cheshire.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon for six months. Board, lodging, and washing in the hospital provided.

WEST LONDON HOSPITAL, Hammersmith-road, W.—Ophthalmic Surgeon. Also Assistant Anæsthetist (honorary and non-resident). Also House Physician and House Surgeon, for six months.

WESTERN GENERAL DISPENSARY, Marylebone-road, London.—Honorary Physician.

Births, Marriages, and Deaths.

BIRTHS.

JAMESON.—On Nov. 3rd, at Titusville, Penn., U.S.A., the wife of Dr. Hugh Jameson, of a daughter.

KENT.—On Nov. 13th, at Lilliesleaf, Lenzie, Dumbartonshire, the wife of R. T. Kent, M.A. Oxon., F.R.C.S. Eng., of a daughter.

LOWE.—On Nov. 13th, at Horninglow-street, Burton-on-Trent, the wife of Walter G. Lowe, M.D., of a daughter.

REES.—On Nov. 12th, at Devonshire-street, Portland-place, the wife of Milsom Rees, F.R.C.S., of a daughter.

TAYLOR.—On Nov. 15th, at the Cottage, Cullingworth, the wife of Tom Taylor, L.R.C.P., L.R.C.S. Irel., of a daughter.

TWEEDY.—On Nov. 15th, at Abbey House, Kenilworth, the wife of Reginald Carlyon Tweedy, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

CARRUTHERS—DICKSON.—On Nov. 11th, at St. John's Church, Burton, by the Rev. C. C. Nation, M.A., Vicar, and the Rev. G. T. Carruthers, M.A., father of the bridegroom, H. J. W. Carruthers, M.D., Moody Hall, Congleton, to Mary I. K. Dickson, elder daughter of F. K. Dickson, J.P., F.R.C.P. E., Wye House, Burton. No cards.

JAMES—RICHARDS.—On Nov. 10th, at Llanstephen, Carmarthen, Gwilym Prosser James, M.R.C.S., of Pencastell, Llanelly, to Amy, eldest surviving daughter of James Richards, of Pantyrathro, Carmarthen.

WADDELOW—HARDING.—On Nov. 11th, at St. Mary's Church, Whittlesey, by the Rev. G. H. Griffiths, John Joseph Waddelow, F.R.C.S. Eng., L.R.C.P. Lond., L.S.A., A.K.C., only son of the late John Waddelow, J.P., to Laura Mary, eldest daughter of the late C. F. Harding, M.D.

DEATHS.

ARMITAGE.—On Oct. 23rd, on board s.s. *Armand Behic*, Joseph Armitage, M.B. Oxon., F.L.S., late of Emu Bay, Tasmania, aged 44 years.

INGLIS.—On Nov. 13th, in London, Alexander Inglis, M.D., M.R.C.S. Eng., L.R.C.S. Edin., of Redball and Auchendinny, Midlothian, and of Montpellier Lawn, Cheltenham, late of Worcester, aged 64 years.

KING.—On Nov. 12th, at his residence, Welford House, Hampstead, Joseph King, M.R.C.S., in his 84th year.

REYNOLDS.—On Nov. 13th, at Douglas-road, Surbiton, Robert Hewetson Reynolds, M.R.C.S., L.R.C.P. Lond., aged 30 years.

SHEPPARD.—On Nov. 13th, at Bognor, Walter George Sheppard, M.R.C.S.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (24th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (25th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (27th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (22nd).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr S. West: Case of Pyopneumothorax of Five Months' Duration Cured by Free Incision, with remarks on the General Treatment of Pneumothorax.—Dr. S. Eccles: The Mechano-therapy of Moveable Kidney.

TUESDAY (23rd).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Discussion (opened by Dr. G. V. Poore): The Prevention of Enteric Fever.

WEDNESDAY (24th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—Papers:—Dr. D Grant: The Diagnosis and Treatment of the Varieties of Dry Cancrum of the Middle Ear.—Mr. J. H. Targett: The Value of the Microscopical Examination of Uterine Curettings.

SOCIETY OF ARTS.—8 P.M. Prof. J. Douglas: Progress of Metallurgy and Metal Mining in America during the Last Half Century.

THURSDAY (25th).—HARVEIAN SOCIETY.—6.30 for 7 P.M. Annual Dinner at the Café Monico.

FRIDAY (26th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Adjourned Discussion on the paper by Mr. A. H. Tubby and Mr R. Jones on Some Cases of Pott's Curvature of the Spine treated by Immediate Reduction of the Deformity. A paper by Dr. Redard will be read and Mr W. Watson Cheyne, Mr. J. Jackson Clarke, and others will speak. Paper:—Mr. C. B. Lockwood: A Case of Radical Cure of Inguinal Hernia, Injury to the Bladder, Formation of Phosphatic Calculi, Lithotrity, Recovery.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

MONDAY (22nd).—LONDON POST-GRADUATE COURSE.—London Throat Hospital (Gt Portland-st., W.), 8 P.M., Mr. G. C. Wilkin: Syphilis as it may affect the Pharynx and Larynx.

TUESDAY (23rd).—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr Craig: Puerperal, Lactational, and Climacteric Insanities.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Drug Eruptions.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. M. Gunn: On Paralysis of the Ocular Muscles.

WEDNESDAY (24th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: Infectious Diseases.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Fowler: The Treatment of Bronchiectasis.

EVELINA HOSPITAL (Southwark Bridge-road, S.E.).—4.30 P.M. Dr. S Fenwick: Marasmus, its Pathology and Treatment (Post-Graduate Course).

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. A. Whitfield: Medical Cases.

THURSDAY (25th).—LONDON POST-GRADUATE COURSE.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. G. Oliver: The Blood.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street W.C.).—4 P.M. Dr. L. Dickinson: Demonstration on Selected Cases.

FRIDAY (26th).—LONDON POST-GRADUATE COURSE.—King's College, 5 to 6 P.M., Prof. Crookshank: Erysipelas and Suppuration.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

ARE SECOND ATTACKS OF MEASLES INFECTIOUS?

To the Editors of THE LANCET.

SIRS,—I am inclined to believe that second attacks of measles are not infectious. My attention was first drawn to the subject by a case which occurred in my practice some fourteen years ago.

CASE 1.—A middle-aged farmer with a large family of children had what was diagnosed as a well-marked attack of measles. I quite expected that some others of the family would be attacked, but to my surprise no one else took it and I concluded I had made a wrong diagnosis. I am not certain that he had had it before, but from the cases I have seen since I am of opinion that he had.

CASE 2.—In 1895 a farmer, middle-aged, had a well-marked attack of measles. He had had measles before. He had five children, and, his being a small house, no effort was made to isolate the case, but no other member of the family took it. In 1896 there was an epidemic of measles in the village; all his five children were attacked, and he again took it in a severe form

CASE 3.—A boy, aged fourteen years, was ill in the same epidemic with his second attack and a child, aged six years, played with him, but did not take it; but six weeks after she contracted it from another child.

CASE 4.—This occurred in my practice in September last. A labourer had a well-marked second attack of measles. He had five children; two of them had not had measles, and although no extra precautions were taken neither was attacked.

I am not aware that this subject has been noticed before, but if my surmise should be correct it would be very satisfactory to be able to assure patients with second attacks that no isolation would be necessary and that there would be no risk to any other persons.

I am, Sirs, yours faithfully,

ALFRED KEBBELL, M.R.C.S. Eng.

"SCARLET FEVER AND THE PRACTICE OF MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 23rd it is recorded that a coroner's jury expressed their opinion "that no medical man should attend midwifery cases while he has contagious complaints in hand." They were investigating the cause of death in a puerperal woman who was thought to have contracted scarlet fever, the infection of which they supposed to be conveyed to her by the medical man who attended her. It is surely advisable that a strong protest should be made against this opinion, for it only requires to be a little fuller grown to lead to a verdict of manslaughter against some unfortunate member of our profession. In the first place, it is utterly impossible for a man in general practice to decline attending confinements or infectious or any other diseases occurring amongst his patients. If the public wishes for such extraordinary protection they must provide each family their own medical attendant, or at the public expense with medical men to attend only scarlet fever or measles or diphtheria, &c. And since all wounds and injuries, as well as diseases, accompanied by suppuration are "contagious" and liable to infect others, they also would be attended by men specially reserved for such duty—a man for each kind of bacillus in fact. Here is a *reductio ad absurdum*. It is counsel of perfection, utterly impracticable and impossible. Amongst the consultants and specialists—who should set an example to the profession and exhibit to the public the very highest excellence in practice attainable—what do we see? What physician gives up all other practice because he has seen a case of infectious disease? What surgeon refuses operations because he has a case of septicæmia? And does the gynæcologist never perform ovariotomy or consult with the practitioner who has a bad confinement until days after he has examined a cancer of the uterus? All their experience teaches them that there is practically no risk if proper measures of cleansing and disinfection are carried out. And so they teach their students and set an example to the profession. Your remark in THE LANCET of Oct. 30th is quite in accord with universal experience. "We must trust to disinfection and scrupulous care, and that these are sufficient to obviate public risk is proved to the hilt by the rarity of the spread of disease viâ the medical man." But to discuss the matter in a more thorough and careful way let us ask a few questions and see if we can find answers. In Twickenham, all the medical men are general practitioners; medical, surgical, obstetric, and infectious cases, all alike they attend. The Infectious Diseases Notification Act has been in force since 1890, so that all cases of infectious disease have presumably been known to our medical officer of health and investigated by him. He has very kindly taken some pains to look up his books and official returns to give me the following facts and figures.

Is scarlet fever often carried by medical men to other patients? During the seven years Mr. W. Marston Clark assures me that in not a single instance has he had reason to think that scarlet fever was due to infection carried by a medical man, not even to a puerperal woman.

Are puerperal women more prone to take scarlet fever than others? We used to be taught that they were, but the above answer certainly affords a strong argument for the negative. And how many cases one remembers to have read in the medical papers when puerperal women were exposed to the infection of scarlet fever in the most concentrated form and neither took the disease nor suffered in any way.

Can the infection of scarlet fever produce any other disease in puerperal women? We used to be taught that it caused often puerperal fever. Rashes are known to occur in septic disease closely resembling those of scarlet fever, measles, &c., and indeed indistinguishable from them, and no doubt many cases of septicæmia and pyæmia (not in puerperal women only) have therefore been called scarlet fever. If scarlet fever produces puerperal fever we should certainly expect to find the notifications of the latter particularly numerous when the former is epidemic. Mr. Marston Clark has given me the following figures:—

Year.	Scarlet fever.		Puerperal fever.	
	Cases.	Prevalent in month of	Cases.	—
1890	43	March	2	1 each in January and August.
1891	38	September and October	3	1 each in January, February, and March.
1892	59	July and October	4	1 each in January, April, July, and August.
1893	187	Epidemic from June to September, 114 cases	3	2 in January and 1 in August.
1894	43	No time prevalent	3	1 each in February, March, and September.
1895	28	Ditto	2	1 each in March and December.
1896	44	None in first quarter, mostly in third	4	1 each in February, March, September, and December.

From this it will be seen that puerperal fever has no obvious connexion with scarlet fever. What does cause puerperal fever? That is a very disputed and unsettled question. Is it merely septic fever due to pyogenic bacteria or sewer gas? Has bacteriology helped to settle it? I cannot find any satisfactory account in any book I have, but the British Institute of Preventive Medicine recommends strongly the injection of antistreptococcic serum, and hence we may conclude that the authorities there are satisfied that many cases are of pyogenic origin. If this is the case, the great danger of the puerperal woman is from the surgical and not from the medical part of practice. It points to the necessity of extra vigilance and care in maintaining aseptic and antiseptic surgery, and in thorough disinfection wherever pus in any form is liable to contaminate the hands or clothes on the part of all those who are likely to be called to a confinement.

I hope that others will add arguments or facts in proof of these contentions—that no practical way of escaping from attending confinements or infectious or any other class of cases by the general practitioner has been proposed or is possible; that medical men rarely carry infectious disease; and that they should not be liable to actions or criminal charges if they have shown proper care and taken reasonable precautions in infectious illness any more than they are when signing lunacy certificates. I am, Sirs, yours faithfully,

Nov. 16th, 1897. H. HOWARD MURPHY, M.D. Cantab.

Mr. L. F. Dods.—The name of the person referred to is not to be found in either the current Medical Register or Medical Directory. He is probably the owner of the name which was removed from the Register some little time since.

COUNTY COUNCILS AND SEWAGE.

WE take the following from the *Leeds Mercury* of Nov. 11th:

> "At the meeting of Barnsley Rural District Council yesterday reference was made to the fact that Staincross police-station was without a supply of water, and it was stated that the County Council had built police-stations at Cudworth and Staincross, totally ignoring the levels of drains and the provision of water-supply, so that the former could not be drained, whilst at the latter station the people had to fetch water a distance of half a mile. A sewage scheme for Carlton township was approved, and plans ordered to be prepared. A scheme on the septic (*sic*) system, to cost about £4000, exclusive of the land, was approved."

LEAD POISONING AND "DR. PRIESTLEY'S COMPOUND."

To the Editors of THE LANCET.

SIRS,—I beg to call your attention to two cases of lead-poisoning which have come under my notice, and which were due, in my opinion, to the partaking of the above proprietary mixture. The first case was that of a woman, aged thirty-one years, whom I saw on Sept. 14th, 1897. She complained of loss of appetite, severe pains in the stomach and in the calves of the legs, and of sickness, headache, and constipation. On examination I found she had a well-marked "wrist-drop," and a prominent blue line on the gums at their junction with the teeth. I further noticed that the pains referred by the patient to the stomach were really at the umbilicus, and were relieved by pressure. On inquiry I found the water-supply was above reproach, and I could not detect any likely source of lead in my patient's diet. She, however, told me that prior to consulting me she suffered from indigestion and had taken two bottles of "Dr. Priestley's Compound," obtained from a local druggist. Under treatment with opium, sulphate of soda, and iodide of potash she recovered completely. My second case is under my treatment at the present time. She is a girl aged nineteen years, who consulted me on Nov. 2nd for the same symptoms as my other case, but the loss of appetite was more marked and the debility greater. I found the "wrist-drop" absent, but the girl complained of a weakness in the wrist-joints. The blue line was very prominent on the gums. This patient informed me that she had taken, before she saw me, a bottle and a half of "Priestley's compound." This case I am treating like the last and the patient is progressing favourably. I brought the remaining half bottle of the mixture home with me and tested it qualitatively, and found it contained *lead*, bismuth, magnesia, soda, and ammonia. Hoping that these facts may be of interest to you and to the profession.—I remain, Sirs, yours faithfully,

WILLIAM SCOTT, M.B. R.U.I.

Kimberley and Eastwood, Notts., Nov. 13th, 1897.

Mr. F. Treece should consult his medical man.

THE PINCESI SAFETY PIN.

WE have received specimens of a modified form of safety pin known as the Pincesi Safety Pin, and consider that the alterations from the usual shape of pin constitute decided improvements. The pin is curved instead of straight, the fastening being on the convexity of the curve, so that a thicker stratum of substances can be impaled with ease than when the pin is straight. The fastening is ingeniously made to enable the point to be received into its shield from openings on both sides of the pin, thereby obviating a little annoyance that many of our readers have doubtless before now felt. For it is a common experience with medical men and nurses to find that when the ordinary safety pin has been nicely brought together and is just going to be pinned the point has not got to the side where the fastening is, and when the operator has only one hand free this occurrence is very troublesome.

AN ENTERPRISING MALINGERER.

To the Editors of THE LANCET.

SIRS,—A man, aged about forty years, calling himself a telegraph operator and signal-fitter, has been discharged from this infirmary as an impostor. He has visited Paddington Infirmary, I know, and probably many other institutions in London are already acquainted with his history. He gives a history of having undergone an operation for ruptured bladder at Montreal, shows a linear scar from the umbilicus downwards, and does his best to simulate peritonitis with hæmorrhage from the bladder. He has learned the trick of registering tall temperatures, but during the four days he was in the infirmary he was usually content with a temperature somewhere about 102° F. It was only once 104°. I have reason to believe that he found his spectacles useful in producing his hæmaturia. There was a remarkably tender spot in the urethra about three inches from the meatus. My object in writing to you is to warn other institutions against this man. It is possible that he has nearly finished with London institutions, and that he will shortly appear in the provinces.—I am, Sirs, yours faithfully,

W. PEMBERTON FOOKS.

Brentford Union Infirmary, Isleworth, W., Nov. 15th, 1897.

P.S.—He was Alfred Waller, aged forty years, at Paddington in August last; John Goeball, aged thirty-eight years, at Isleworth.

THE OWENS COLLEGE DEBATING SOCIETY.

AT the first meeting for the session of the Owens College Debating Society the subject for discussion was Vivisection. Mr. R. A. Needham, who introduced it, dealt with the character of the opposition, and pointed out numerous cases in which vivisection had been of use both to men and animals, and argued that "the superiority of man was sufficient to justify its practice morally." He moved: "That in the opinion of this house experiments on living animals are scientifically useful, morally justifiable, and have proved of very great service in the alleviation of human and animal suffering." A full discussion took place, and an amendment was proposed and seconded, but the resolution was carried by 36 votes to 8.

W.R.—"Lectures on Medicine to Nurses." By Herbert Cuff, M.D. Lond. (London: J. & A. Churchill, 1896). "Notes on Medical Nursing." By the late James Anderson, M.D. Aberd. (London: H. K. Lewis, 1897).

A HARD CASE.

To the Editors of THE LANCET.

SIRS,—Having been a subscriber to your valuable columns I take the liberty of sending you these few lines, in which I state my case. I have been a medical practitioner in this place for more than twenty-eight years, during which period I have held most of the principal appointments. When the Settle and Carlisle railway was in construction I was appointed contract surgeon for the entire period (namely, seven years). At its completion I applied to the Midland Railway Company for the post of surgeon in this district—which I got, and held for twenty years—and had to resign this and other appointments on account of failing eyesight. I may also add that I was medical officer and public vaccinator for this district for eight years, during which period I received two grants from the Local Government Board for having given most satisfaction out of four other local medical officers. I have been totally blind for the last two years. I still hold the office of medical referee for the Prudential Assurance Company, which one year with another for the last twenty years has brought me in £3 per annum. Could you kindly inform me if there is any fund in the medical profession from which a little pecuniary assistance might be obtained under the circumstances? Apologising for the space I have taken,

I am, Sirs, yours faithfully,

REGINALD R. DUDLEY.

Kirkoswald R.S.O., Cumberland, Nov. 15th, 1897.

"SIGHT-TESTING FOR THE GENERAL PRACTITIONER."

MR. F. DAVIDSON, of 120, Great Portland-street, asks us to state that the work bearing the above title, of which he is the author, and which was noticed in THE LANCET of Oct. 23rd, is to be had only from him, and *not* from the printer, whose name we accidentally inserted as the publisher. Mr. Davidson is desirous that this announcement should be made, as his book is intended for medical men only, and not for the general public.

"WANTED A REMEDY IN SEVERE LUMBAGO."

To the Editors of THE LANCET.

SIRS,—In reply to "L.R.C.P." in THE LANCET of Nov. 13th, I can strongly recommend a mixture composed of tinctura hyoscyami, liquor potassæ and potassii nitras (say half a drachm, forty minims, fifteen grains to the ounce), to be administered every four hours for twenty-four hours and then three times a day. Locally, flannels wrung out of *boiling* water and laid on a folded sheet in bed; then *freely* sprinkled with turpentine; patient to place the lumbar region on the flannel and be well covered up. This application may be repeated every ten or fifteen minutes till the parts assume the colour of a boiled lobster. I have found these remedies to be very successful.

I am, Sirs, yours faithfully,

Nov. 16th, 1897. W. B. H.

"A DEATH FROM CIGARETTE SMOKING."

To the Editors of THE LANCET.

SIRS,—Noticing your remarks on this subject in THE LANCET of Nov. 13th we beg to call your attention to the fact that we recently tested for arsenic some cigarettes which a friend assured us had made him ill, and we found an appreciable quantity of arsenic in the tobacco. The paper was free from arsenic. We have had considerable experience in testing our colours and wall-papers for arsenic, and having for our own protection, not without great trouble, obtained a supply of reagents of absolute purity, the accuracy of our test may be implicitly relied upon. We are, Sirs, yours faithfully,

Nov. 13th, 1897. WM. WOOLLAMS AND CO.

"INVERSUS" WOOLLEN UNDERCLOTHING.

MR. D. GILBERT, of 7, Buckingham Palace-road, S.W., who submitted to us summer substances for vests and drawers which were referred to in THE LANCET of June 12th last, page 1649, has now sent to us similar garments made up in the thicker or winter substance of the same material. It may be useful to repeat that the special feature of the "Inversus" material is its exceptional smoothness and entire absence of the knots and teazles usually associated with woollen underclothing, thus meeting the difficulty of those whose skins are so sensitive as to preclude their wearing the ordinary woollen garment by reason of its irritating effect.

GOVERNMENT MEDICAL APPOINTMENTS.

To the Editors of THE LANCET.

SIRS,—I should feel obliged if you or some of your readers would inform me if there is any published book or pamphlet where one can ascertain the medical appointments which are at the disposal of the Government in its various departments. I am told that such information in a printed form exists, but my informant cannot recollect where he has seen it. I am, Sirs, yours faithfully,

Nov. 9th, 1897. AN OLD SUBSCRIBER.

*** The Medical Directory (on p. 20 of the current issue) publishes this information under the heading, "Principal Appointments held by Medical Men." Whitaker's Almanac gives supplementary information concerning some of the appointments. We do not know the book to which our correspondent alludes, but think that such a work would be very useful.—ED. L.

Edina.—Our correspondent must supply us with a more detailed account of the incident to which he refers. There is a University of Chicago which grants the degree of M.D. after a four or, at least, a three years' course.

A BREACH OF MEDICAL MANNERS.

THE *Bethnal Green News* of Nov. 13th has been sent to us by four local practitioners, and our attention has been called to an article therein which describes the virtues and capabilities of "Dr." Alfred H. Parker, who has recently, it appears, acquired a practice in the Roman-road. The article in question is illustrated by a reproduction from a photograph of its subject's "genial features" and its contents form a very fulsome advertisement of Mr. Parker, so much so that we have no hesitation in saying that if Mr. Parker supplied the *Bethnal Green News* with the necessary materials for its composition he has committed a grave breach of medical manners. It is necessary for his good name's sake that he should at once repudiate any knowledge of this article in which a distinct attempt is made to dower him with extraordinary talents to the manifest prejudice of his professional brethren whose honour, not to say whose good taste, prevents them from making similar degrading bids for public support.

During the week marked copies of the following newspapers have been received: *Wellingborough News, Devon Gazette, Accrington Observer, Bradford Observer, Scotsman, Glasgow Herald, Times of India, Pioneer Mail, Newcastle Leader, Dundee Advertiser, Colchester Mercury, Essex Telegraph, Liverpool Daily Post, Preston Guardian, Hereford Times, Eastern Morning News, Cambridge Express, West Briton Advertiser, Worcester Herald, Architect, Builder, Birmingham Gazette, Sussex Daily News, Leicester Post, Warwickshire Times, Walsall Advertiser, Yorkshire Post, Poole Herald, Northampton Herald, Isle of Wight Observer, Bridgwater Independent, Grimsby News, Bristol Mercury, Westminster Gazette, Lincoln Mercury, Western Morning News, Portsmouth Times, Leeds Mercury, Brighton Gazette, Sanitary Record, Dumfries and Galloway Standard, Local Government Chronicle, The Surveyor, City Press, Mining Journal, Norwich Mercury, Reading Mercury, Hertfordshire Mercury, Public Health, Engineer, Surrey Advertiser, Local Government Journal, Weekly Free Press and Aberdeen Herald, Guernsey Star, Hastings and St. Leonards Observer, Lynn Advertiser, Manchester Guardian, Loughborough Monitor Shrewsbury Chronicle, Waterford Chronicle, Cambridge Daily News, West Middlesex Herald, Northwich Guardian, Salcombe Times, Tadcaster News, Mid-Counties Express, &c. &c.*

An Oration

ON

EMPIRICISM OR SCIENCE?—ANÆSTHETICS, 1847–1897.

Delivered before the Society of Anæsthetists on Nov. 18th, 1897,

BY DUDLEY W. BUXTON, M.D., B.S., M.R.C.P. LOND.,

ANÆSTHETIST IN UNIVERSITY COLLEGE HOSPITAL AND TO THE DENTAL HOSPITAL OF LONDON AND THE HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, BLOOMSBURY.

LADIES AND GENTLEMEN,—No great scientific discovery has been made without bloodless battles having been fought and adverse champions drawn up in army array. The discovery of anæsthesia is no exception to this statement. Even now the clarion notes of the fierce fight ring clear through the air and men's minds grow warm with angry despite as they hear the cry of battle from opposing ranks. Man is a fighting animal, and while he strives to assuage the sufferings of poor humanity he finds solace in pointing out the folly of those whose opinions he traverses and whose positions in argument he assails, crying, "No quarter; No surrender." Nor has the fight been one of individuals; there has been a contention of nations. We meet to-night to celebrate the fiftieth anniversary of the introduction of chloroform, to do honour to its champions, to range in line the growing wealth of knowledge which for half a century has accumulated about the practice of anæsthesia. As an outcome of this the question rises into prominence and presses for an answer—Is the whole art and science of the medical man who practises in anæsthetics a matter of empiricism, or has he the right to claim for his calling the proud distinction of a science and for his practice the equally aspiring title of a precise art? Dr. Robert Davis,[1] speaking on the interesting occasion of the semi-centenary of the first public demonstration of the use of sulphuric ether as an anæsthetic, insisted upon the point that the discovery of anæsthesia was no accident. Yet the history is fraught with many strange things which show how near many men came to the bourne of discovery but returned unenlightened, and how nearly did those who eventually won the laurels awarded to discovery turn aside and relinquish the quest. Davy, Horace Wells, Faraday, Crawford Long, are names which leap into the mind. Davy, who actually inhaled nitrous oxide gas and realised its anæsthetic properties at the close of the last century; Faraday, who actually suggested that sulphuric ether should be employed for the assuaging of pain in 1818, as Davy had done for nitrous oxide; Samuel Guthrie, of Brimfield, Massachusetts,[2] prepared chloroform but left its discovery as an anæsthetic to Sir James Y. Simpson. Long used ether in 1842 and even placed patients under its influence for surgical operation, but as he failed to communicate his experience to the world the public proclamation of ether was left to Morton. Claimants to a knowledge of the properties of the various anæsthetics have been many. There is no doubt that all great discoveries are in the air—if I may be allowed the expression—even before the man of the hour comes forth and fearlessly takes the world into his confidence and announces his discovery. That man is the true benefactor of his day and generation and whatever may have been the assistance he has derived from those who went before he still remains the centre figure and justly is placed in a niche in Fame's temple.

It has been well said that to realise to the full the benefits of anæsthesia we must recall the days of surgery before 1846. A vivid enough picture is given in Professor Miller's "Surgical Experiences of Chloroform." He recalls how Abernethy before an operation had exclaimed. "I feel as if I was going to be hanged"; while Cheselden turned sick at the thought of the pain he was about to inflict and Liston lay awake in mental anxiety on the eve of his operation days. If surgeons grew faint, alas for the patients! Speaking of the patient it is said, "His progress might be traced by frightful yellings or at least by sobs of deep distress, and occasionally a number of stout assistants scarcely sufficed to prevent on the way a self-effected rescue and escape. All this was bad, painful, injurious, unseemly. All such scenes are now unknown."[3]

The wife of a distinguished surgeon recalls how terrible were the sounds with which her ears were assailed as seated in the rooms of her residence within the precincts of a large London Hospital she heard the cries of the unanæsthetised patients on the one hand and the moans of the no longer dumb beasts passing into Smithfield upon the other—sounds, too dreadful to be recalled without a shudder. Simpson, like many another, quailed before the ordeal of carrying on surgery under such conditions and decided against medicine as a profession. However, he found law still less to his taste, and in 1836 while house-surgeon to the lying-in hospital at Leith he sought means whereby the pangs of suffering humanity could be alleviated. Mesmer had been born a hundred years before this, and although the fraud of his pretensions had been exposed by the celebrated commissions appointed in France to investigate animal magnetism, yet Cloquet, Loysel, and other surgeons had actually performed surgical operations on hypnotised subjects. Herbert Mayo, surgeon to the Middlesex Hospital, and Elliotson, some time physician to St. Thomas's and University College Hospital, both of whom, alas, paid with their professional ruin for their enthusiasm for hypnotism, wrote on the mesmeric sleep about this time (1837). Braid and others contended that in the mesmeric trance was to be found the panacea for surgical suffering, if not a universal therapeutic armamentarium. Simpson employed the mystic passes of Braid's neurohypnology. He never, as far as I know, employed hypnotism for surgical anæsthesia. However, with Morton's successful demonstration before Warren, Bigelow, Gould, Parkman, Hayward, Townsend and the younger Warren, ether was flashed forth upon the world as the desideratum hoped for so long. Oliver Wendell Holmes invented the word and "anæsthesia" was an accomplished fact. It would be as tedious as it is unnecessary for me to attempt to describe the various causes which very rapidly led surgeons to regard ether with some disfavour. The methods of giving it were very inexact, many failures occurred; anæsthesia was too often an interchangeable term for wild maniacal excitement, and the operator had to use his knife with much deftness to avoid doing his patient a mortal injury as he struggled and fought under the exhilarating effects of an inadequate amount of ether vapour. Majendie[4] spoke contemptuously of it, alleging that the operation done under ether "was an experiment performed on intoxicated subjects, some of whom were rendered unconscious of pain while some were not"; a patient, he alleged, sprang from his couch while an operation was in progress and shook his gory hand in the face of the surgeon and his assistants. Some persons recommended a sort of full dress rehearsal of the proceedings. The patient was to inhale ether to see how it affected him, and if the result was satisfactory the process was repeated and the operation performed. Three deaths had been reported by March, 1847,[5] and while many surgeons declared the use of ether a dangerous innovation the Canton of Zurich actually promulgated an order that its use should be discontinued. "In fact," says a writer at this date, "it is a question in all men's minds—Is not the use of ether in operations too uncertain and dangerous a resource surgically to be had recourse to?" Many of the rules and precautions then suggested would surprise members of this society. Let me mention two. On no account, we are told, should an inhalation of ether be continued for more than a quarter of an hour or should more than two ounces be inhaled! Simpson, however, hailed with acclaim the new anæsthetic and gave ether to a lying-in patient on Jan. 19th, 1847 and with his usual promptitude communicated his experience on the following day to the Obstetrical Society of Edinburgh.[6] He at once commenced his experiments upon various drugs

which might prove possible anæsthetics. Simpson, George Keith and Matthews Duncan met after dinner at Simpson's house and inhaled the anæsthetic and were in due time rendered more or less insensible.[7] Thus were tried "chloride of hydrocarbon, perchloride of formyle, acetone, nitrate of oxide of ethyl, benzin, and other vapours."

An incident of what may be called an accidental character was the use by Jacob Bell and Mr. Lawrence in London and by Bigelow in America of chloric ether or chloroform dissolved in spirits of wine. Had Bell only gone one step further chloroform would have been an accepted anæsthetic. One of Morton's first essays had been with this substance and possibly he suggested its employment to the surgeon. However, the results obtained were uncertain and little attention was attracted to the substance, so little indeed that when Simpson asked Waldie what substances were worth experimenting with from the point of view of anæsthesia he appears not to have heard of Bell's trials of chloric ether. Now happened another "chance occurrence." Waldie failed to supply the promised sample of chloroform, and but for Mr. Hunter, of Messrs. Duncan and Flockhart's, Simpson's inhalation of chloroform might have been indefinitely delayed or even not made at all. As it was the experiment was made, and Simpson thus describes it: "I had the chloroform for several days in the house before trying it, as after seeing it such a heavy, unvolatile-like liquid, I despaired of it, and went on dreaming about others."[8]

Simpson was from the first firmly impressed with the view that in chloroform he had found the crowning height of anæsthesia, although his mind was too free from bigotry not to look for and hope for a still more perfect anodyne. Beyond the experiments made upon the bodies of himself and his friends Simpson appears to have felt no call for physiological inquiry into the properties of this wonderful discovery. He collected statistics and studied his cases but there the matter ended. His teaching, however, was very definite and derived from his personal experience, and as it is seldom quoted correctly I may here give his own words: "When used for surgical purposes perhaps it will be found to be most easily given upon a handkerchief gathered up into a cup-like form in the hand of the exhibiter and with the open end of the cup placed over the nose and mouth of the patient. For the first inspiration or two it should be held at a distance of half an inch or so from the face and then more and more closely applied to it. To ensure a rapid and perfect anæsthetic effect, more especially where the operation is to be severe, one or more teaspoonfuls of the chloroform should be at once placed upon the hollow of the handkerchief and immediately held to the face of the patient. Generally a snoring sleep speedily supervenes and when it does so it is a perfect test of the superinduction of complete insensibility. But a patient may be quite anæsthetic without these symptoms supervening."[9]

Syme, whose dicta upon this subject have been accepted as the rallying point of the Edinburgh school, has not given any account of any scientific explanation of the action of chloroform, nor have I been able to ascertain that that illustrious surgeon did more than epitomise his views of chloroform in a clinical lecture delivered during the winter session of 1854-55 in his class in the University of Edinburgh. After dealing somewhat severely with the methods of giving chloroform in vogue in London he goes on to say: "I am very far from taking any credit to myself. All I have done has been to follow the example of Dr. Simpson." Syme insisted that the London method failed because it did not carry out Simpson's directions. He says: "The points that we consider are of the greatest importance in the administration of chloroform are, first, a free admixture of air with the vapour of chloroform, to ensure which a soft porous material such as a folded towel or handkerchief is employed, presenting a pretty large surface, instead of a small piece of lint or any other apparatus held to the nose; secondarily, if this is attended to the more rapidly the chloroform is given the better till the effect is produced; and hence we do not stint the quantity of chloroform. Then—and this is a most important point we are guided as to the effect not by the circulation but entirely by the respiration; you never see anybody here with his finger on the pulse while chloroform is given. So soon as the breathing becomes stertorous we cease the administration; from what I have learned it is sometimes pushed further elsewhere, but this we consider in the highest degree dangerous. Attention to the tongue is another point which we find of great consequence. When respiration becomes difficult or ceases we open the mouth, seize the tip of the tongue with artery forceps and pull it well forward; and there can be little doubt that death would have occurred in some cases if it had not been for the use of this expedient. We also always give the chloroform in the horizontal position and take care that there is no article of clothing constricting the neck. There are thus considerable differences between our practice and that which prevailed more or less elsewhere. We use no apparatus whatever, take the respiration for our guide, attend to the condition of the tongue, and never continue beyond the point when the patient is fully under the influence of the anæsthetic."[10]

Syme's success in the use of chloroform is a matter of history, but his method was empiricism. Although he taught that the respiration rather than the circulation was the guide to be followed I gather from Professor Buchanan that Syme never expressed himself upon the subject of heart failure under chloroform. Simpson, however, did this, and did it very emphatically. In his first paper, 1847, he said that chloroform "if given in too great or too long continued doses would doubtless produce serious consequences and even death," and writing in February, 1870, Simpson narrated a case of death under chloroform when he gave the anæsthetic with his own hands. The death was that of a young woman and it occurred in the small village hospital at Alloa. He says: "I chloroformed the patient. In doing so I placed a single layer of towel over the nose and mouth leaving the eyes exposed, and dropped chloroform upon the towel." During the first incision "the patient moved so much that he [the surgeon] stopped for a brief time till I put the patient more deeply under the effects of the anæsthetic." The patient vomited suddenly and profusely during the operation. "Immediately the eyes opened the pupils were preternaturally dilated, the face looked pallid, and the respiration which had never been affected by the chloroform so as to have the least noise or stertor in it seemed arrested. Immediately artificial respiration was set on foot and the tongue pulled forward. Deep, spontaneous respiration then occurred several times in succession and I deemed at the moment that the patient was hence out of danger, but a second collapse occurred which terminated in death, all means of resuscitation proving unavailing." Remarking upon this occurrence Simpson said: "According to all the experimental and clinical observations which have been made chloroform appears capable of destroying life in two ways, namely (1) by asphyxia and (2) by syncope. Death by asphyxia can generally, if not always, be avoided by at once arresting the inhalation of the drug whenever the breathing becomes noisy or stertorous, states which, as already mentioned, never occurred with the preceding patient. Syncope or sudden stoppage of the action of the heart is doubtless far less under control and has apparently formed the principal cause of fatal issues in almost all cases in which patients have perished when under the use of chloroform."[11] The courage and honesty of the man are wonderfully brought out by the prompt publication of this death under his hands, and Simpson's claim to our unstinted admiration is certainly strengthened when we look at him not only as a discoverer, as a patient and conscientious observer, but as one who felt that to suppress facts averse to any theories of safety which he might have held would be a departure from that high standard which he had always set before himself in his professional career. When I say "discoverer" it must be clearly understood that I claim for Simpson not the discovery of chloroform, for that was made by Samuel Guthrie an American, by Soubeiran a Frenchman, but the discovery of its anæsthetic powers and its introduction into the practice of surgery. Simpson contended that syncope occurred under chloroform and had occurred in pre-anæsthetic days, and although he did not waver in his adhesion to his first method of giving the anæsthetic he yet cautioned his followers against a foolhardy belief in the extreme safety of this powerful drug which he had been the means of bringing into use.

On Nov. 10th, 1847, the famous paper, "Notice of a New Anæsthetic Agent as a Substitute for Sulphuric Ether in Surgery and Midwifery," was read before the Obstetrical Society of Edinburgh and chloroform made its bow before

the world. To us it is almost incomprehensible that chloroform should have called forth the most rancorous opposition and acrimonious criticism from those who undertook in the words of the most sacred of writings to prove that at best chloroform was a snare of the arch enemy of mankind. We can now afford to smile at such well-meant twaddle, for even yet at the end of the nineteenth century we have to show patience towards and wish that greater enlightenment should come upon those persons who in the name of religion seek to check experimentation and sap the tree of knowledge by peddling appeals to an hysterical and ill-informed coterie of sentimentalists. The powerful advocacy of Simpson and the Edinburgh surgeons soon carried chloroform beyond the shallows of its period of trial and the new anæsthetic became an accepted agent. At this time there were no very clear views entertained about its physiological properties and Flourens in France and Snow in England undertook careful research into its mode of action. The classical researches of Flourens and Longet had early in the "forties" shown the order in which the component parts of the nervous system yielded before death occurred. So long as the medulla remained guarded the organism was held to be safe. With the advent of anæsthesia came a host of theorisers who spent valuable time in elaborating hypotheses designed to explain the mechanism of narcosis. Thus we find the observers Lallemand, Perrin, and Duroy teaching that chloroform possessed an elective affinity for the nervous tissues. Flourens, indeed, regarded chloroform as a most dangerous body and inveighed against its use in surgery. He had, however, employed a vapour with a very high percentage of chloroform with a very fatal result.

Various theories more or less beside the truth were started connecting anæsthesia with blood changes. In 1848 Snow commenced his papers on Narcotism by the Inhalation of Vapours, and with his work a nearer approach to physiological investigation of the action of anæsthetics was inaugurated. He sought to show that chloroform acted according to the dose administered and according to the dilution practised. Simpson's rules as far as they went laid down a safe basis for administration, but the *rationale* underlying that safety was only elucidated by the work of Snow and his successors. While Simpson found experience from his practice upon his fellow human beings, courageously placing himself first in all such experiments, Snow adopted a safer and more satisfactory plan of using the lower animals—more satisfactory because test conditions could be imposed. His experiments are fully set forth in his classical work on Anæsthetics, a monumental book written by one of the world's great men. Snow's experiments, which were made upon small mammals and birds, led him to the following conclusions. He used the term "narcosis" as designating the entire effects of the chloroform upon the nervous system, restricting that of "anæsthesia" to mere deprivation of feeling. He taught that various *degrees* of narcotism were produced by certain definite quantities of the anæsthetic. "The division into degrees is made according to symptoms which I believe depend entirely on the state of the nervous centres and not according to the amount of anæsthesia, which there is good reason to conclude depends to a great measure on the local action of the chloroform on the nerves."

This was a distinct advance in our knowledge and was derived entirely from experimental data. The animals experimented upon were placed in chambers which contained enough air for their vital requirements and were subjected to various strengths of chloroform vapour, and the symptoms they evinced were carefully noted. With such facts before him Snow attempted to show that, given the weight of the animal and the vital capacity of its lungs, the temperature of the air and its moisture, it was possible to predicate that a definite series of phenomena would ensue upon the inhalation of a given quantity of the anæsthetic. This was perfectly true as far as it went. The fallacy arose from a disregard of the personal equation of the individual as regards power of respiring, predisposition to syncope, &c. This fallacy, as we shall see, Snow was fully aware of. He further taught that "when inhaled the local effect of chloroform must be greatest when it has had time to exude through the coats of the vessels into the extravascular liquor sanguinis and come into immediate contact with the nervous fibrillæ. As the brain is without lymph and lymphatics it is possible by a large dose of chloroform to produce complete anæsthesia very suddenly before there is time for the nerves to be acted upon locally to any extent." Snow found that when the dose was sufficient the patient passed from his fourth degree into the fifth, in which respiration failed and the heart continued to beat, until it also ceased owing to stoppage of breathing. However, Snow went further, for he adds: "Although the respiration may be suspended by an amount of chloroform which has very little direct effect on the motion of the heart, it is quite possible to stop the heart's action by the immediate effect of this drug." When warm-blooded animals breathe air containing as much as 8 to 10 per cent of the vapour of chloroform the blood which is passing through the lungs becomes so charged with it as to stop the action of the heart when it reaches that organ through the coronary arteries." He also noted that injection of chloroform in water produced loss of muscular irritability and finally post mortem rigidity.

Snow spoke with no uncertain voice in dealing with the action which chloroform exerted upon the circulation. The pulse, he says, "affords no criterion of the amount of narcotism," for even under formidable operations its volume and force remain unaltered. One is struck here, as whenever studying the work of this remarkable man, that his conclusions have in most cases anticipated those of the later and most accomplished experimentalists, and if some of his experiments were crude and his instruments lacking in precision his breadth of reasoning and intuitive grasp of results always placed him on the level of those who with the modern and perfected apparatus of the physiolcgical laboratory have attacked the subject with appliances so exact as to render error almost an impossibility. Snow conducted some experiments with Sibson which led him to believe that section of the vagi made no alteration in the procession of phenomena observed when chloroform was inhaled. Reverting to his experiments undertaken to discover the amount of chloroform requisite to plunge the patient into the various degrees of narcotism we may note that while between one and two grains of chloroform in each 100 cubic inches of air induced surgical anæsthesia, two grains plunged the patient into the fourth or paralytic degree and led to gradual failure first of the respiration and subsequently of the circulation, while three grains caused respiratory failure. He acutely perceived that in warm-blooded animals the problem became a much more complicated one. Not only does Nature safeguard us by lessening the force of respiration and the rapidity of circulation and so stays the intake and deportation of chloroform from the lungs to the heart and the tissues but also exercises a species of check action through the nervous mechanism of the medulla oblongata which tell for the safety of the individual and the diminished intake of the poison. Allowing as far as he could for these controlling and overriding conditions Snow showed that 12 minims of chloroform equally distributed in the circulation of an individual of average weight led to the second degree of narcotism, 18 minims to the third and 24 minims to the fourth, while 36 minims caused respiration to stop. Snow pointed out the obvious disadvantage of Simpson's recommendation of a handkerchief for giving the anæsthetic since he urges that it is impossible by such a method to regulate the proportion of vapour to air which the patient breathes. To Simpson and his school who did not appreciate these facts it was of no moment what quantity of anæsthetic was used provided sufficient air was allowed to enter the lungs to maintain the respiration and sufficient vapour inhaled to obtain anæsthesia. With Snow it was a first principle that you should be able to regulate to a nicety the dose you gave and to limit it exactly in every case. To effect this Snow carefully devised his chloroform inhaler. With it he achieved at least as great a success as did those who, failing to grasp Snow's science, sneered at his inhaler. I may here allude to more recent experiments undertaken by one whose name has been identified with chloroform and whose fame has alike honoured him and the profession he has adorned—I mean Lord Lister. Lord Lister, then Mr. Joseph Lister, in 1861 undertook some very clear experiments [12] and found that the rate of evaporation from a cloth under the test conditions was in point of fact below the danger limit fixed by Snow. Ingenious, however, as are these experiments they are inconclusive, since, although they show the gradual evaporation of a known quantity of the anæsthetic maintained under test conditions as regards temperature, moisture, &c., they do not allow for the sometimes reckless "spilling of two or three drachms" on the handkerchief referred to by

[12] Anæsthetics, in Holmes's System of Surgery, p. 601.

Miller in his "Experiences of Chloroform." The regular and philosophic breathing of the experimentalist who respires beneath a chloroformed cloth in such a way that his inspirations are carefully guarded against taking in the narcotic vapour are hardly quite comparable with those of the average patient about to undergo a mortal operation and who inhales into his lungs a vapour which at first is pungent but grows less so until the person in charge of the "handkerchief, towel, piece of lint, worsted glove, nightcap, or sponge" (I quote Professor Miller again) deems it right to again "spill" another two or three drachms upon the extemporised inhaler. Snow's science taught him that the less you left to the caprice or individual ability of the person giving the chloroform the safer would it be for the patient. He showed that 18 minims of chloroform in the lungs meant not quite 300 cubic inches of vapour in combination with air, the whole of which would be inhaled in twelve breaths. If the inhalation of this strength of vapour were continued until insensibility a large quantity of vapour would remain unabsorbed in the lungs. The 250 cubic inches of air contained in the lungs if saturated with chloroform at 60° F. would contain 30 minims of chloroform. Even if only half of this was saturated the patient would fall into deadly peril. Although the pulmonary air would in practice seldom become so saturated it is evident that the degree of saturation of a towel and the vigour of respiration—as for example a deep breath following a period of apnœa—would expose a patient to danger which would be avoided were the method of giving the narcotic one which limited the supply within the physiological requirements of the patient. The dangers of struggling, the immense importance of watching the respiration, and the deepening of narcosis for twenty seconds after inhalation of chloroform has ceased were all taught by Snow. Sedillot[13] appears to have made an almost simultaneous discovery of this last fact. Snow again made careful notes on the condition of the eyes and the pupils, although his conclusions were more vague than most of his utterances.

Snow recognised various forms of death as resulting from chloroform inhalation and reproduced them in the lower animals. Thus (1) he induced death by *gradual* absorption of a quantity of chloroform (36 minims) given in a low percentage vapour (below 6 per cent.) sufficient to paralyse the nervous control mechanism of respiration, while (2) he found that if a higher percentage of vapour (8 to 10 per cent.) were suddenly caused to enter the pulmonary circulation this excessive strength would upon entering the coronary vessels paralyse the heart itself before the nerve centres were subjected to the influence of the anæsthetic. Under such circumstances very few respirations were sufficient to cause enough vapour to enter the pulmonary air cells for the lethal 36 minims to be pumped into the circulation. Working upon cats and rabbits with low percentage vapours (3 to 6 per cent.) the respiration failed before the circulation; with vapours of 8 to 10 per cent. a simultaneous cessation occurred of respiration and circulation or the heart stopped before the breathing. In the first class of cases the animals were restored by access to air; in the last artificial respiration failed to resuscitate them.[14]

Snow proved that this heart failure took place wholly without impediment to the pulmonary circulation and was associated with a dilatation of the heart which at a certain point became paralytic. In his experiment he showed that when an excessively high percentage vapour (10 per cent.) is inhaled from the first death from cardiac paralysis may and does ensue before anæsthesia is ever attained. This, he says, is an example of many cases of deaths of human beings. Again, death may occur after inhalation has been left off, and this point he again illustrates by experiments.

Perhaps no feature of Snow's work is more remarkable than his criticism of the fatalities, the reports of which he collected. He brought them into line with his experiments and showed with consummate mastery of his subject the factors which in each case determined the fatal result. In 1848 Sibson did much valuable clinical work upon the subject of chloroform and performed a number of experiments upon the lower animals which throw much light upon the mechanism of death under chloroform.[15] Sibson's views were in accord with those of Snow: Sibson devised the facepiece which Snow adopted for his chloroform inhaler and which allowed free respiration through its valves and was a pronounced improvement of many of the apparatus then in use.[16]

The review of the cases of death led Snow, as it had led Sibson,[17] to believe that most if not all such fatalities were due to paralysis of the heart. In death from asphyxia the heart beats for from one to three minutes after the breathing has come to a standstill, and as he pertinently remarked: "It is extremely improbable that anyone would go on giving the vapour after the breathing became stertorous and laboured."[18] In 1855 a Chloroform Commission was instituted in Paris and published[19] a conclusion that in the lower animals the heart always goes on beating after respiratory paralysis. Thus they agreed with the experiments undertaken by Mr. Thomas Wakley, of THE LANCET, who upheld that cardiac failure under chloroform was not met with in the lower animals. Snow, however, had encountered it and he impugned the results above referred to. He based his opposition firstly upon his experiments on the lower animals which had convinced him that all deaths due to chloroform inhaled when the vapour was over 5 per cent. resulted from circulatory failure. However you might alter the conditions, provided the strength of the chloroform vapour remained constant, syncope occurred without interference with respiration or signs of asphyxial complications, death even occurring before insensibility had shown signs of appearing. When, however, a low percentage vapour was employed—that is, one below 5 per cent.—the various degrees of narcosis always and regularly showed themselves. He asserted that only when chloroform gradually accumulated in the blood to such an extent that the total quantity reached more than his lethal dose of 36 minims, death followed from what he called narcosis of the brain with failure of respiration through poisoning of the medullary centres. Furthermore, he analysed all the cases of death of which particulars had been accessible, and in his review of them he showed conclusively that with four exceptions they were deaths from cardiac failure and not from respiratory paresis. In other words, the symptoms were those of circulatory failure and not of pulmonary engorgement. To put the whole matter briefly, Snow's position was this: if you introduced a certain dose into the organism uniformly diffusing it throughout the circulation you produced given phenomena which eventually poisoned the various vital controlling systems of the animal, respiration and then circulation being the last to go. If, on the other hand, you introduced a large dose into the lungs in such a way that it was absorbed and passed directly to the heart, that dose conveyed through the coronary arteries paralysed the heart and so the animal died at once. In the first case—the asphyxial death—the employment of forced respiration may eliminate the poison; in the second the tissues of the heart actually being killed no restorative measures are from the first destined to be of the slightest good.

Patrick Black, who wrote a pamphet in 1855 and who was, I believe, one of the first anæsthetists appointed to a London hospital, contended that chloroform did not kill even when presented in overwhelming doses, for he said "we have only to attend to the breathing, we may disregard all considerations affecting the relative proportion of chloroform and of air which is breathed ..... if the patient breathes easily he is in safety whatever be the amount of chloroform which is passing in his lungs." His argument was that the patient was strangled by the strength of the vapour which prevented his inhaling and prevented his breathing. This position Snow at once showed was untenable because the actual experiment revealed that animals could breathe a high percentage of chloroform and that it was impossible for an individual to hold his breath even against an irritant, and further it was inconceivable that such a mistake could be made as to imagine a patient voluntarily holding his breath against an unpleasant vapour when he was dying from the effect of that vapour. Black, who was assistant physician to St. Bartholomew's Hospital, was a distinguished man who upon his appointment to the full office of physician appears to have left the turmoils of anæsthetic warfare. Unfortunately a death occurred in his practice in which it was shown that the source of danger

was that which he pointed out could not have arisen and so the *argumentum ad hominem* applied. Nor did Snow admit the various theories which were invented, such as special idiosyncrasy, theories of the fear of the surgeon's knife, and so on which were brought forward to explain chloroform fatalities. It will be impossible in the time at my disposal to do justice to the amazing amount of experimental and careful clinical work which was accomplished by Snow; perhaps the most pronounced compliment that can be paid to his memory lies in the fact that all the modern researches which have been made and which have stood the test of criticism have been based upon, if not forestalled by, Snow's earlier labours. To him was the initiation though to others the full fruition of his researches and conclusions.

Among the early workers in the field of anæsthetics was Thomas Nunneley, of Leeds, who experimented with benzine, carbon disulphide, carbonic acid gas, carbonic oxide, but whose name is perhaps best known in connexion with his advocacy of bromide of ethyl as an anæsthetic. He also tried olefiant gas (ethene), ethyl chloride, turpentine and contributed to the literature of the subject of anæsthesia. In June, 1864, a committee composed of T. B. Curling, Thomas Bryant, Samuel Cartwright, Arthur Farre, George G. Gascoyen, George Harley, Prescott Hewett, F. W. Mackenzie, William Marcet, Charles H. Moore, James Paget, William O. Priestley, Richard Quain, Francis Sibson, R. Dundas Thomson, Charles West, Septimus Sibley, George W. Callender, and John Birkett was appointed by the Royal Medical and Chirurgical Society to inquire into "the uses and physiological therapeutical and toxical effects of chloroform as well as into the best mode of administering it and of obviating any ill consequences resulting from its administration." Experiments were made upon the lower animals and different percentages of vapour employed. The conclusions arrived at were that for moderate and small doses little difference was observed whether the chloroform was inhaled above or below the glottis.

Under such circumstances respiration stopped first, although not always, and though in the majority of cases the pulse ceased before the respiration the actual heart beat could be felt for some time longer. The importance of this lies in the fact that they appear to have recognised that the heart becomes enfeebled before the circulation comes to a standstill; in other words, it is a poisoning of the heart muscle as opposed to the poisoning of the medullary centre. This committee worked with a hæmo-dynamometer, but the readings were taken by the eye and not by the sensitised plate. They further noticed that incoördinate movements of the heart occurred even after effective contraction had ceased, a condition which later MacWilliam noticed and explained. However, in one important particular the Committee took a line at variance with Snow's findings and equally at variance with more recent but more exact research. They thought that the effect upon the heart of a strong vapour of chloroform was not materially different from that produced by a milder form of the agent. But what appeared to have been their meaning was that the accumulation of a small dose tells upon the myocardium eventually in quite as deletrious a manner as a large dose taken by a few deep inspirations, and this no doubt is true when working in the lower ranges of chloroform vapour. They arrived at the result which I believe has been uniformly found by all observers who have investigated the effect of chloroform upon the respiration, that when inhaled sufficiently long and insufficiently diluted the respiration failed and was finally extinguished. That is always assuming that the dilution is sufficient not to tell initially upon the heart. Their conclusions as to the physiological effects of chloroform are summarised as follows: "The sequence of the phenomena produced by chloroform inhalation in animals is similar to that observed in man; and if the same percentage of the agent be administered the results produced are nearly uniform. Chloroform at first increases the force of the heart's action; this effect is slight and transient. When complete anæsthesia is produced by chloroform the heart in all cases acts with less than its natural force. The strongest doses of chloroform vapour, when admitted freely into the lungs, destroy animal life by arresting the action of the heart. By moderate doses of chloroform the heart's action is much weakened for some time before death ensues; respiration generally, but not invariably, ceases before the action of the heart and death is due both to the failure of the heart's action and to that of the respiratory function. The danger attending the use of chloroform increases with the degree of stupor it induces. Apparent irregularities in the action of chloroform mainly depend on the varying strength of the vapours employed, on the quality of the chloroform, and on the constitution of the patient." The report further contained the account of some experiments as to the best means of resuscitation as well as statistics and an account of chloroform in midwifery practice. While they regarded chloroform as a dangerous and somewhat unmanageable agent, they placed it before ether, since ether as then given was a slow and uncertain anæsthetic, and they adopted as a middle course the well-known A.C.E. mixture, which they regarded with great favour—a mixture which was suggested by the late Dr. Harley.[20] With regard to ether, although they thought that its action was similar to that of chloroform they asserted that they never succeeded in producing failure of circulation by its use except in cases where respiration had been brought to a standstill. They appear to have overlooked that the methods employed not only lead to the inhalation of ether, but also cut off an adequate supply of air. Snow, who had conducted similar experiments, had found that the lower animals would inhale almost pure ether vapour without syncope occurring, and that even if respiration failed through narcotisation of the medullary centre the forced entrance of a breath or two at once restored the vital processes in every case. It is a curious reflection that even as late as the date of this report it was necessary to gravely consider whether or not chloroform interfered with the healing of amputation wounds and increased or lessened the after-mortality of operations. The teaching of Arnott and other distinguished surgeons had been strongly adverse to the use of anæsthetics and that teaching still lingered. The report, I need hardly say, went dead against any theory that chloroform interfered with the after success of surgical procedure. Associated with this report was the name of the late Mr. Joseph Thomas Clover, who in 1848 had been appointed resident medical officer at University College Hospital. His work, good as it was, was rather upon the side of practice than of experimentation. Perhaps no man has done more to remove the slur passed upon ether by the report which we have just considered. If ether was a slow and uncertain drug before Mr. Clover's ingenious brain devised his inhalers and perfected his methods no such stigma could be attached to it afterwards. These drawbacks were wholly removed by Clover. Snow had given up ether for chloroform, but gave up chloroform for amylene, and after having the misfortune of two deaths under that reagent he again reverted to chloroform. Benjamin Ward Richardson, then a young man full of enthusiasm and eager to follow in the lines Snow had laid down, was working upon the subject of anæsthesia, and it was he who pointed out to Snow that amylene was a most dangerous form of narcotic. "I ventured," said Richardson, "to show him separation of amylene in the blood, a separation which looked like the formation of minute plugs. He fully realised the danger."[21] A glance at the *Æsculapiad* for July, 1884, will serve to show the amount of work which Richardson did in the field of general anæsthetics. His overmastering idea was that general anæsthetics were doomed sooner or later to give way to a more perfected form of local anæsthesia, and although he experimented and published the results of his experiments with chloroform, ether, bromide of ethyl, amyl chloride, amyl hydride, butyl chloride, carbon bisulphide, and other agents, his most known work is rather in the field of local anæsthesia and so need not be dealt with in the present connexion.

In 1866 Robert Ellis suggested his plan of giving a mixture of the vapours of alcohol, chloroform, and ether. In 1879[22] were published the first instalments of the report of a committee of the British Medical Association dealing with the action of anæsthetics. This committee consisted of Joseph Coates, William Ramsay, and John McKendrick, and thus comprised a pathologist, a chemist, and a physiologist, and is commonly spoken of as the Glasgow Committee. They dealt with a large number of substances, they were able to employ more exact methods and more reliable physiological instruments, and I believe for the first time adopted the graphic method of recording their results. It may be said in passing that although to describe their experiments in detail is beyond the scope of our present purpose, yet they were most carefully performed and as far as they went were accurate. They may be

summarised in the following way. The blood-pressure under chloroform is reduced while unaffected under ether. "Chloroform has sometimes an unexpected and capricious effect on the heart's action, the pressure being reduced with great rapidity almost to *nil*, whilst the pulsations are greatly retarded or even stopped. The occurrence of these sudden and unlooked-for effects on the heart's action seems to be a source of serious danger all the more that in the two instances they occurred more than a minute after the chloroform had ceased to be administered and after the recovery of blood-pressure." I have quoted the passage because it seems to me to be the least satisfactory portion of the report. It is inconceivable that any physiological action can be termed capricious or at least can be accurately termed capricious. Chloroform they found killed dogs either by stopping respiration or circulation, but as far as I can gather the effect to which they refer is upon the medullary centres rather than to the direct action upon the heart muscle, and they seem to assume that the individual peculiarity of the animal is responsible for cardiac failure occurring in some instances and respiratory in others. A great deal of their report is occupied with the consideration of ethidene dichloride, a drug which Snow had introduced and of which he thought highly. It cannot be said that the report of the Glasgow Committee carried the work of Snow much further. It would appear that they lost sight of to a great extent the all-important question of dosage and did not bring out with sufficient prominence the different physiological consequences of vapours of various strengths. However, the work was to be carried forward by others with equal enthusiasm.

The final epoch of the scientific work of the fifty years of chloroform now completed is grouped about the Hyderabad Commissions and much of the splendid research owes its origin directly both to the munificence of the Nizam of Hyderabad and the enthusiasm of Surgeon-Lieutenant-Colonel Lawrie, while owing indirectly to the same source very much of the later and valuable work of the past few years has been called forth by the Commissions. MacWilliam's research on Paralytic Distension of the Heart,[23] Gaskell and Shore's report on the Physiological Action of Chloroform (1893), Hare and Thornton's Study of the Influence of Chloroform upon the Respiration and Circulation, and Leonard Hill's research upon the Influence of the Force of Gravity on the Circulation of the Blood[24] and the same worker's brilliant address delivered before this society early in the present year[25] and Waller's ingenious investigation into the Action of Narcotic Vapours on Nerve Tissue have advanced our knowledge of the physiological action of chloroform by leaps and bounds. The excellent clinical work which had been done and recorded by Snow, Sibson, Nunneley, Richardson, Clover, Sansom, and more recently by the British Medical Association and THE LANCET Commissions had enabled us to guess at the behaviour of this potent narcotic while the research work, a rapid glance at which has been attempted in the earlier portion of this address, confirmed the conclusions of clinicians, yet as these authorities differed it was difficult to reconcile the results. With the more recent experimental work, although a certain variation in conclusions exists the actual facts are all automatically recorded and are open books for all to read and form an opinion upon. It is impossible to attempt a detailed account of the methods adopted in the research undertaken at Hyderabad. Suffice it to say the animals subjected to chloroform were placed in as nearly a parity of circumstances with human patients as possible. Briefly, the position assumed by the Commission was—(1) that chloroform always produced a fall of blood-pressure, and (2) that under sufficiently diluted vapour the respiration, the action of the heart, and the rhythm and force of the pulse remain unaltered. When variations in the gradual fall of blood-pressure, the performance of respiration, and in the action of the heart take place they are due to direct overdosing or to overdosing through abnormal or irregular respiration. While overdosage cannot occur it was contended that if certain simple rules were followed and the state of respiration be accepted as the one and only criterion of the degree of chloroformisation, it was advanced that when an overdose was intentionally given the animal died but never through any circulatory disaster. In all their experiments in which the animals died the respiration failed before the heart. They were led to believe that surgical shock was completely abrogated by the use of chloroform, nor did they admit that accumulation of chloroform ever took place in the blood so long as the respiration remained free. Lastly, they denied that the muscular tissues were directly affected by chloroform but only through gradual and progressive narcotisation of the nervous centres.

The theory of the action of chloroform thus built up becomes attractive and simple. Give chloroform highly diluted with air it will gradually lessen blood-pressure so that the circulatory system becomes an automatic check system, lessening and lessening the rate at which the narcotic is carried to the central nervous system and so safeguarding the organism from harmful over-narcotisation. As the nervous centres pass under the influence of the chloroform the various phenomena of paralysis occur in the order described by Majendie, Flourens, and Longet and the medullary centre presiding over respiration at length is put to sleep When breathing stops the blood fails to circulate through the lungs, the heart becomes affected, its intrinsic vessels empty, and as it grows more and more anæmic its action grows more and more feeble and at last fails. If, however, the necessary condition of free respiration is non-existent this procession of events does not take place. Permit anything to occur which causes asphyxial phenomena, says the Commission, and you at once bring about vagal action. The heart stops, the blood-pressure lowers. This state of affairs is, however, a blessing in disguise. It is, in fact, a series of protective reflexes which prevents the excessive dose of chloroform entering the nervous centres; when it passes off, which it will always do, this inhibition will be found to have saved the patient's life.

The theory thus perhaps somewhat baldly expressed has been severely criticised, has been tried in the balance by some and found wanting. No doubt if the Commission's premises are admitted their conclusions remain sound enough. It is upon the question of fact and not of theory that issue has been joined. Starting with the blood-pressure, all admit that it is lowered by chloroform. The Commission believe that this is due not to heart failure or to vaso-motor paralysis, and is of its nature pre-eminently protective. The lowering of blood-pressure, if not due to vagal stimulation or dulling of the medullary centres, must arise from vaso-motor paralysis leading to emptying of the arteries into the veins—"the loss of arterial tone" of Snow—or to failure of the heart itself. Recent observers have asserted that one or other or even both these are contributory causes which bring about the result and base their assertions upon experimental evidence. Chloroform has certainly been shown to depress the vitality of protoplasm in weak vapour while a strong vapour will destroy it totally. The blood corpuscles and the muscular tissue both striated and non-striated are also affected by chloroform. The work of Lorraine Smith seems to lend colour to the suggestion that the corpuscles are so influenced as to lessen their power of conveying oxygen to the tissues. Ringer and others have shown that the frog's heart removed from all nervous influence is gradually paralysed by very weak chloroform solution perfused through it and that eventually it loses all contractility. MacWilliam in a most striking series of experiments has striven to prove that, quite independently of all complicating circumstances such as asphyxia, partial or complete, all strengths of chloroform act directly upon the heart muscle causing paralytic dilatation. At a certain point this dilatation becomes incapable of correction, the heart then no longer contracts, and the circulation fails. This cardiac dilatation further occurs independently of vaso-motor action and determines a gradual failure in the force of the heart beat from quite the commencement of the inhalation. This must lead to impoverished blood-supply not only to the heart muscle itself, but to the various nerve centres concerned in the mechanisms of life. It must be remembered that section of the vagi makes no difference to this dilatation, nor can the old theory of pulmonary engorgement due to vaso-constriction explain the condition. Professor Dastre states, but without experimental evidence, in his work on Anæsthetics that a constriction of the pulmonary veins occurs when chloroform is inhaled leading to distension of the right heart. Were such a theory even proved it would fall short of explaining the phenomena, as all the cavities of both sides of the heart are dilated under chloroformisation only those of the right side. MacWilliam found, as [illegible] had previously pointed out, that the relation of the time occupied in inhaling any given amount of chloroform is

[24] Ibid., 1890.

Digitized by Google

of great moment. The even distribution of a considerable quantity of chloroform in the blood is far less dangerous than a much smaller dose suddenly introduced. His experiments show most conclusively the danger arising from irregular breathing, which means an unequal intake of the vapour. In natural respiration about 20 cubic inches might be inhaled and during a very deep breath 100 cubic inches, so that a dilution adequate for natural breathing would be about five times too potent for the deeper form of respiration. Nor is this a matter of slight importance, for MacWilliam's experiments proved how small a quantity of chloroform would prove a lethal dose if rapidly taken. A similar unequal rhythm of respiration was also found to occur, thus adding a further liability to the intake of an overdose.

The most original research of Gaskell and Shore, who pursued another method, that of cross circulation, brings still further evidence in the same direction. They were able to show that so far from the lowering of blood-pressure being due to the action of chloroform upon the vaso-motor centre it arose entirely from the weakening effect which the chloroform exerted upon the heart muscle. The vaso-motor centre was always in their experiments stimulated by chloroform to produce vaso-constriction with a consequent increase in blood-pressure. Again, although the research of Hare and Thornton[26] supports the findings of preceding workers in some respects it adopts a middle course in the main questions at issue. They think their experiments prove that in the lower animals respiratory failure is always the cause of death when the heart is sound. They, however, found "injection into the jugular veins of more than 2 to 4 c cm. of chloroform caused arrest of inspiration rapidly followed by cardiac arrest, which was not secondary to the respiratory failure but to a primary action of chloroform upon the heart muscle." But they find there is always a fall of blood-pressure under chloroform, which they regard as being as great a source of danger as is respiratory narcosis. There is, they contend, always a distinct depression of the cardiac muscle with dilatation of the organ such as MacWilliam described. And although they consider this depression is not sufficient in itself to cause death, yet they add: "We believe that gradual asphyxia with the direct depression of the circulation may do much towards producing a fatal result, for vaso-motor integrity is always as necessary to life as an intact cardiac mechanism." Although Dr. Lauder Brunton, it may be presumed, holds in the main the views of the Hyderabad Report, which he signed, yet his more recent contributions to the discussion appear to show that he with Hare and Thornton considers that when any asphyxial phenomena are developed such as would ensue upon weakening of the respiratory centre the animal may die from circulatory failure before true respiratory narcosis supervenes. The weak point in this position is that while everyone from Snow downward has conceded the necessity for free dilution of chloroform vapour and the avoidance of any asphyxial phenomena the crux has always been how to avoid the vascular depression. The Hyderabad Commission frankly accepts the position by denying that vascular depression ever entails danger; but Hare and Thornton, Gaskell and Shore, and all recent workers not only hold the opposite view, but actually point to the Hyderabad tracings in support of their assertions. It is the clinician, who is not always a *persona grata* to the physiologist, who now steps in and assures us that it is practically impossible to say who has a healthy heart or shall we say who has a resistive heart. Abuse of living, hard living, scanty diet, terror, wasting disease, are factors in the problem which face the anæsthetist, but, like Gallio, the physiologist cares for none of these things. Hare and Thornton in their report say: "The variation in the action of a drug on a diseased individual from its effect on the normal one is notorious, and we have no right to dogmatically assert that there is no danger of circulatory depression in man even if we found no evidence of failure in dogs, because there may be many idiosyncrasies or variations, through disease in the human being which may completely reverse the results of experiments on healthy animals." They find from a long series of experiments that "gradual cardiac failure never occurs without producing respiratory changes from the very first." But of course all who have experimented upon the lower animals and have given chloroform to the higher readily admit this. It is not the gradual but the rapid cardiac failure which is to be feared. Leonard Hill,[27] however, has been led to modify the view that respiration fails initially while circulation is subsequently and consequently paralysed in chloroform death. His experiments go to show that when chloroform is inhaled the arterial pressure falls rapidly and as it touches a certain point near the zero line respiration ceases. On removing the chloroform the arterial pressure slowly rises from the excitation of the asphyxial blood and respiration starts again. It is the fall of blood-pressure due to circulatory depression which leads to respiratory failure, since the medullary centres no longer supplied with blood cease to perform their work and breathing ceases. In this view artificial respiration, our sheet-anchor in chloroform emergencies, is valuable not so much by virtue of its power to aerate the lungs, but because it pumps the blood from the lungs into the left heart and so into the coronary vessels. Hill concludes that spinal bulb anæmia from lowered arterial pressure is the cause of respiratory failure as is shown by the fact that raising the arterial pressure always leads to return of respiration. He makes this important point: "The depth of anæsthesia depends as does the paralysis of the respiratory centre on the primary fall of the arterial tension."

"There are two forms of chloroform syncope: (*a*) During primary anæsthetisation the patient struggles, holds his breath, raises the intrathoracic pressure congests his venous system, lowers his arterial tension, and finally takes deep inspirations and surcharges his lungs with chloroform. In the first stage the heart becomes impoverished, in the second stage it is suddenly filled with blood. This is drawn from the lungs and is full of chloroform. The chloroform passes into the coronary arteries and the heart is thrown into paralytic dilatation. Respiration and the pulse either cease simultaneously or the pulse before respiration. (*b*) During prolonged anæsthetisation this arises from gradually giving chloroform to too great an extent. The arterial pressure falls lower and lower, and secondarily the respiration ceases because of the anæmia of the spinal bulb. The heart is not in this case paralysed by chloroform because the drug is taken in gradually by the shallow respirations and distributed slowly by the feeble circulation." Waller has further shown in a series of very beautiful experiments, many of which I have had the advantage of seeing, that chloroform acts powerfully upon nervous tissue. It not only reveals a strength of action seven times that of ether, but very rapidly destroys the irritability of the structure. It is interesting to see from these experiments that chloroform stands forth declared the most potent and therefore most lethal of anæsthetics. As Simpson had almost prophetically said in 1847 chloroform combined within itself almost infinite powers for good and evil. All the work of fifty years has but taught us that in spite of the advertisements of instrument makers and the assured utterances of doctrinaires chloroform is in all hands a dangerous anæsthetic. The teaching of fifty years, the teaching, I would say, rather of Snow than of Syme, still remains unshaken. To give chloroform safely we have to first dilute our vapour and then observe that even the diluted vapour is not inhaled too rapidly. Lawrie has said: "The Hyderabad Commission's work proves that, while Syme's principles are right, there is no such thing as a safe method of chloroform administration. It is no longer a question of the superiority of the London method or of the Edinburgh method; absolute safety can be obtained neither by watching the respiration nor the pulse for signs of danger, which are in either case proof of improper administration or of overdosing. Moreover, overdosing may take place whether the anæsthetic is given on lint or on a towel or on a cap such as we use, or with Junker's or Skinner's or any other form of apparatus. The all-important point is that the breathing shall never be interfered with in any way. Safety under chloroform can unquestionably be ensured, but it can only be so by attending to regular natural breathing; and whatever method is employed no one can deny that it is the bounden duty of the chloroformist to maintain natural breathing throughout the whole period of administration. To maintain natural breathing requires careful training and considerable experience; but if these conditions be fulfilled it is impossible to produce anything with chloroform but anæsthesia, and the Hyderabad Commission has shown that anæsthesia alone is

[26] A Study of the Influence of Chloroform upon the Respiration and Circulation, by H. A. Hare, M.D., and E. O. Thornton, M.D., being a report to Surgeon-Lieutenant-Colonel Lawrie and the Government of H.H. the Nizam of Hyderabad. Detroit, Mich.: G. S. Davis. 1893.

entirely free from risk,"—and his utterance is in the main correct. If it were possible to ensure this natural breathing the safety of chloroform would indeed be assured, but as MacWilliam, Gaskell, and Hill have now proved a fall of blood-pressure may jeopardise the patient and bring about the respiratory failure which every anæsthetist strives to avoid. I am fully aware that very many important researches, such as those of Bernard, Best, Anstey, and the names of many workers have found no place in this address. My excuse must be that the literature of chloroform has become so enormous within the semi-centenary now completed that it is impossible even to catalogue them in name much less to describe in detail the works themselves or the results arrived at. I have attempted to group our thoughts around the most striking figures—the men of the hour which these fifty years have brought forth. It has been my aim to deal with the strictly scientific rather than the clinical side of the question and to place before you the physiology rather than the practice of giving chloroform.

What, then, ladies and gentlemen, have we to show for these fifty years of work? Are deaths less frequent from chloroform? Do we understand its physiological action better? Are we mere blind leaders of the blind working empirically with a drug of which we know little, inhaled into and acting upon the organism in a way of which we know less? I venture to say the answers to all such questions are at least re-assuring. Unhappily we cannot say the mortality as a whole is less. Many circumstances account for this. In the first place a regrettable familiarity with the stoppered bottle and the always accessible towel or handkerchief has relaxed the sense of responsibility which once the giving of chloroform entailed. It has been wittily said that even the youngest of us make mistakes and certainly very many fatalities under chloroform would be prevented if only experienced persons were called upon to use chloroform to produce surgical anæsthesia. Again, the methods in vogue are usually faulty. The accomplished chloroformist will use the rudest means of bringing about chloroform sleep with impunity, but to leave the dose of anæsthetic and the degree of dilution to the judgement of the inexperienced house surgeon or dresser is to court disaster. No doubt the teaching of Syme and the practice of Lawrie are absolutely sound—their results prove it; but so did the results of Snow support his teaching that the sitting posture was as safe for chloroform inhalation as the recumbent; so did the results of Clover, who at one time gave chloroform from lint and covered the patient's head and shoulders with a towel, a procedure which Snow did not hesitate to condemn. But all these methods depend upon the individual who pursues them. To the average equestrian the performances of the circus rider are feats of danger and bristle with endless chances of accident and death. So is it with chloroform. Unless I have failed utterly in my endeavour to place before you the light and leading of the past fifty years you have realised that chloroform has been proved beyond dispute, alike by its friends and its foes, to be a most powerful and therefore most perilous drug. Therefore, unless you can make all chloroformists as expert and as conscientious as Simpson, Snow, Syme, Clover, and Lawrie, you must either restrict the use of the drug to those who at least have such responsibility as engenders care or supply better methods than those which leave so much to the personal intelligence of the chloroformist.

Perhaps the strongest feeling caused by the annals of these fifty years are those of gratitude to the great men who introduced chloroform and of gratitude to those whose patient toil and untiring energy have taught us the physiology of the action of chloroform on the organism. Knowledge casteth out fear. The empiric trusts to rule of thumb, scorns to learn the possible results of his actions, and possesses a courage born of ignorance. To the man of science—and I venture to say that no man should more emphatically make himself a man of science than he who undertakes to administer anæsthetics—knowledge means the power to avoid recognised dangers, to guard against their coming and be ready to counteract them when they arise and to guide his patient through safe paths to anæsthesia. He should be fearless because forewarned and only fearful lest through carelessness or loss of that professional conscience—his sense of responsibility—he sins against knowledge, placing a slavish adhesion to precedent before the all-important necessity of studying each case as it comes and before adapting his measures to the ever-varying conditions of that ever-changing problem—the human body.

Supplementary Croonian Lecture

ON

POINTS CONNECTED WITH THE PATHOLOGY AND TREATMENT OF DIABETES.

Delivered before the Royal College of Physicians of London on Nov. 11th, 1897,

BY F. W. PAVY, M.D. LOND., LL.D., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

(*Concluded from p. 1301.*)

WHATEVER may be the means by which it is effected it may be regarded as certain that to keep the sugar proceeding from the food out of the urine it must be kept out of the general circulation. The power by which this is accomplished falls within what we understand to be meant by the term assimilative power and it is through this power being at fault that in diabetes sugar gets into the urine from the food. In proportion as the power in question is diminished so is there a diminution in the amount of carbohydrate that can be taken without influencing the urine. The position of things may be exemplified by a vertical column representative of the power under consideration with the maximum degree, or that belonging to health, standing at the top and successive stages of decrease, corresponding with what may be found to exist in different cases of diabetes, following on below until we arrive at the bottom where the power is *nil*. The maximum power is such as to be sufficient for providing for the disposal of the carbohydrate that is taken within ordinary limits, and thus it happens that under these circumstances no influence is exerted upon the urine. If carbohydrate, however, should be taken to an undue extent, and especially if introduced into the stomach in a soluble form and at a period of fasting, the tax upon the assimilative power surpasses the capacity to meet it, and as a result, notwithstanding we are in the presence of a healthy system, a portion escapes being disposed of and is permitted to reach the general circulation as sugar and in this state to find its way into the urine. This may be looked upon as the explanation of the saccharine urine which it is known can be induced in both man and the lower animals by excessive ingestion of carbohydrate.

With rather less assimilative power existing than is normal a given amount of carbohydrate that can be taken by a healthy person without producing any noticeable effect gives rise to glycosuria. Cases of this nature are not unfrequently met with in practice and prove perplexing to the medical man and to the patient. By one practitioner the patient is told that there is sugar in his urine and for a while he may be inspired with gloomy forebodings. He possibly later seeks the opinion of another practitioner who pronounces his urine to be perfectly right, and by this he is consoled till it arrives that he is afterwards told again that there is sugar in it. This apparently puzzling state is entirely due to the carbohydrate that may happen to have been ingested just previously to the urine being examined. When in excess of a certain limit sugar is voided; when, on the other hand, below it no sugar is found, the assimilative work to be performed being within the capacity existing for performing it. Like to what has been said with regard to the healthy person, saccharine and non-saccharine urine follow in response to the particular amount of carbohydrate ingested. The only difference between the two cases is that an amount of carbohydrate that suffices to lead to the production of saccharine urine in the glycosuric does not suffice for doing so in the healthy person. It is to be remarked that the effect is noticeable within two or three hours after the food has been taken. Before the meal there may be no sugar in the urine and a short time afterwards a more or less notable amount may be discoverable. These are the cases that are frequently referred to as cases of intermittent diabetes. The intermittent character noticeable is due to variations that may happen to occur in connexion with the food.

So it runs on. Different grades of power are met with in different cases and it is found that an amount of carbohydrate that one glycosuric may be able to take without its

Digitized by Google

leading to the passage of sugar suffices to determine its escape in another. The person has his fixed limit of power just as we as healthy subjects have, but the limit of power stands lower and is of varying degree in different cases. In each instance, as long as the carbohydrate taken is within the capacity existing of assimilating or properly disposing of it, the urine remains uninfluenced; whilst when the capacity has been exceeded sugar becomes discoverable, the quantity standing in relation to the extent to which the capacity has been surpassed. A case at a given time may be advancing in the direction of loss or in the direction of gain of power, but taken at other times the steadiness that is noticeable from day to day, week to week, month to month, or even year to year, is most striking. The patient has his fixed point of assimilative power. In addition to the restricted diet for the diabetic he may be able to take a certain weighed quantity of ordinary wheaten bread without sugar appearing in the urine. In other cases the quantity that can thus be taken may be larger and larger. The limit belonging to the case is ascertainable by observation and subsequently the state of the urine will depend upon whether carbohydrate is taken to a greater or to a less extent than the equivalent of that contained in the specific quantity of bread found to be permissible. When the patient is living close up to his boundary line sugar is apt upon occasions to be met with. This, from the variation that is liable to occur in his daily food looked at in its entirety, is only what may be reasonably expected. When, however, thoroughly below his boundary line there is sufficient assimilative capacity to spare to cover any little variation and prevent the urine being influenced.

It is not for a moment to be understood that in the restricted diet there is a complete exclusion of carbohydrate matter. Even purely animal food contains a certain amount, and in the substitutes for bread variable quantities according to circumstances exist. All that can be accomplished is to carry the exclusion as far as is practically consistent with the provision of a supply of food that the patient can satisfactorily eat and subsist on. As the object of the restricted diet is to reduce the supply of carbohydrate matter so that if possible it may fall within the assimilative capacity existing, it is of paramount importance that we should be able to rely upon the articles that are sold to take the place of bread. Without security in this matter the dietetic treatment of diabetes may not merely prove fruitless but at the same time absolutely misleading to the medical practitioner. Unfortunately, either from ignorance or unscrupulousness, articles are put into the market for sale as appropriate food for the diabetic which are literally no more suitable for the purpose than the food they are designed to replace. Both medical man and patient require to be vigilantly on guard to escape from the infliction of grievous physical harm and subjection to vexatious disappointment. Even with foods of the better class character considerable variation exists in the produce (particularly the gluten flour and thence what is derived from it) of different makers, and want of success in treatment may result from the article employed not being of the degree of purity looked for. Fortunately the high-class makers of diabetic foods in this country are fully alive to the importance of conscientiously attending to the question of purity, and the more this is realised and acted up to the better the position in which the medical practitioner is placed. It must be acknowledged that the matter is not devoid of difficulty. Palatableness has to be looked to and ordinarily palatableness suffers at the expense of purity. The art called for is to produce food which is palatable and at the same time suitably constituted to meet the requirements of the complaint. The producer has at one and the same time to use his endeavours to please the patient and satisfy the physician, and amongst those who have exerted themselves in a right way to attain the object desired I consider Mr. Callard deserves to be mentioned.

The state of the urine constitutes a tell-tale in relation to the food that has been taken, and errors in diet in whatsoever way occurring are unfailingly revealed. A reliable quantitative determination of the sugar is of course required for the purpose, and with a specimen of urine taken for examination from that passed on going to bed at night and another from that passed on rising in the morning, the one being under the influence of the food of the day and the other under that of fasting during the night, we obtain a disclosure, if there is any to be made, of the effect of what has been ingested. The night specimen is under the influence especially of the food taken in the latter part of the afternoon and the early part of the evening, and from this circumstance it is not unfrequently found to contain sugar whilst the morning specimen may be free. On the other hand, should food be taken shortly before bedtime—in other words, should the last meal be a supper at the end of the evening instead of a dinner at the early part of it—the position may be reversed through sufficient time not having elapsed for the night specimen to be influenced and the effect of the food being thrown instead on the morning specimen. Under such circumstances sugar may be found in marked amount in the morning urine and less or none in that passed at bedtime. So sensitive is the urine to the influence of food that in the case of a glycosuric requiring a strict observance of the restricted diet for maintaining the urine in a sugar-free state the starchy matter contained in a thin water biscuit may suffice to impart to it a distinctly saccharine character. Whatever the nature of the article containing the carbohydrate it equally tells upon the urine, but on account of the solubility of sugar in contra-distinction to starch articles containing the former produce a more speedy effect than those containing the latter. I need not dwell upon the delusion so extensively prevalent that toast from bread is allowable when bread itself is not, or that the starchy matter of the potato stands in a different position from that from other sources.

Removal of sugar from the urine by reducing the carbohydrate taken does not mean cure of the disease. What is wanted for cure is restoration of the assimilative power, and in proportion as this is brought about so can more and more carbohydrate be taken without leading to the passage of sugar. If, indeed, in a diabetic case the power should become fully restored the patient would be placed in a position to be able to take the ordinary diet without its influencing his urine, and he might then be truly told that he had shaken off his complaint.

But control of the elimination of sugar by diet is of paramount importance in promoting improvement, and may be looked upon as an indispensable measure of treatment. It is not the mere fact of the waste of food occurring with the discharge of sugar that constitutes the great source of trouble in diabetes. It is the state of system which stands as a preliminary factor to the elimination that occurs. The blood forms the connecting link between the urine and the food. The sugar present in the urine has previously passed to it through the blood, and in doing so has created in this fluid a deviation from the natural state which tells injuriously throughout the entire system. It is not natural for the blood of the general circulation to contain more than a certain small amount of sugar, an amount varying but little under healthy circumstances. With the presence of an increased quantity as a result of the faulty assimilation of the carbohydrates of the food it is thrown into an unnatural state and its constitution altered in such a way as to interfere with its fitness for ministering to the proper performance of the nutritive and various other processes of life. All the symptoms and results of the complaint depend upon the unnatural presence of sugar in the contents of the circulatory system, and on this condition being altered, as it is shown to be by the disappearance of sugar from the urine, the symptoms and ill-effects immediately subside. It may then be said that so long as this state can be maintained the patient has nothing to fear from diabetes. Diabetic coma is the condition most to be dreaded as an issue of the disease. With the sugar in an uncontrolled state the condition is liable at any time to supervene and speedily carry off the patient. If any other complaint of an acute nature, as influenza, pneumonia, &c., should set in, great danger is incurred of a fatal termination through the supervention of diabetic coma. A diabetic in the great majority of instances does not die in a direct manner from the superadded complaint, but from the development of diabetic coma. Not so, however, when the elimination of sugar is thoroughly under control. Such a patient is to all intents and purposes except in relation to food in the same position as an ordinary person. In all my experience I have never come across the supervention of diabetic coma in a case where the urine has previously been in a sugar-free state.

To control the escape of sugar by adaptation of the diet is only a rational procedure and cannot be otherwise than right. There is a diminished assimilative power existing, and to bring the conditions to a properly balanced state there should be a corresponding diminution in the class of food

Digitized by Google

calling for the exercise of the power. When the amount of carbohydrate matter of the food is shaped so as to be properly adapted to the power existing of disposing of it there is no disturbance of the required harmony between the two, and the system escapes being prejudicially influenced by the effect of the deficient power that has to be dealt with—escapes, in other words, being thrown into an unnatural state by the presence within it of sugar which ought not to be there. The passage of sugar that can be controlled by reduction of ingested carbohydrate means neither more nor less than the unnecessary infliction of harm, and the harm inflicted stands in proportion to the amount of sugar that is allowed to reach the system and thence to escape with the urine. The fact of voidance of sugar affords evidence that the system is already overburdened with carbohydrate and any addition will have the effect of increasing the abnormal condition existing. If the case is one in which the sugar in the urine is not susceptible of removal its reduction in quantity does good by establishing within the body a closer approach to the natural state.

As I have asserted, what is to be sought for by treatment is the restoration of assimilative power over the carbohydrates and this is often demonstrably attainable. Let me give an illustration of the kind of case I am not unfrequently meeting with in my experience. A patient, say, above middle age has become diabetic, but from some cause or other does not happen to fall under proper treatment till he has reached a very bad state. His symptoms have been persistently growing more and more marked, and at the time of falling under observation he may be suffering from great thirst, passing an enormous quantity of urine, and having become much reduced in weight and strength. We will suppose that he is placed on the restricted diet, which is loyally attended to, and that codeine, opium, or morphia is administered. Even within a few days a marked change is produced. The thirst and excess of urine subside and the patient picks up in weight and strength. The sugar falls and ultimately disappears. In some instances this happens with surprising rapidity, but in others it may not be till after the lapse of some days or even of a longer time than this, that the urine is found to have lost its saccharine character. The satisfactory progress continues. The patient feels as though he had shaken off his complaint and perhaps wonders why he should have to keep to his measures of treatment. Any relaxation in diet, however, would immediately lead to a return of sugar. The power of disposing of carbohydrate matter has not yet become restored. For a while the improvement is well maintained, the weight, which in the first place underwent increase, being afterwards kept up. Later, but when cannot be foretold, a change may set in which is not unlikely to excite gloomy forebodings by leading to the apprehension that a relapse has occurred. It may be at the end of some weeks, or more likely months, a decrease of weight may set in and the patient may feel weaker and be reminded of the state that existed before the treatment was commenced. If with this alteration the urine continues free from sugar it may be read off as a sure sign that a restoration of assimilative power has commenced to take place. A return to ordinary food would indubitably bring back the sugar. The improvement of power that has occurred is only likely to be slight and requires to be met by a correspondingly slight allowance of carbohydrate matter. It appears to me that bread is the article most missed from the ordinary dietary, and this therefore I am in the habit of suggesting for employment as a representative of carbohydrate food. I begin with 3 oz. per diem in portions of 1 oz. at each of the three principal meals. Under the circumstances depicted it may reasonably be expected that no sugar will be made to appear in the urine, and, such being the case, in the course of ten days or a fortnight a trial is made of 1½ oz. in place of 1 oz. three times daily. This also is ordinarily found to be tolerated, the indication of toleration being that the carbohydrate does not pass off as sugar. Interesting to note, with the administration of the bread the patient immediately begins to recover his lost weight and to feel himself again. Later another drop in weight may occur, and it is to be taken as an indication for a further increase of bread. In this way I frequently work up during a space of, it may be, two or three months to 7 oz. or 8 oz. of bread per diem. I sometimes find that the capacity exists for the quantity to be raised to 9 oz. or 10 oz., and I have known cases where I have been able to proceed as far as 12 oz., and upon rare occasions a greater latitude of diet than even this involves has been unattended with the passage of sugar. If sugar should reappear in the urine it must be looked upon as meaning that the mark has been overstepped and that a retrogression must be made to the quantity found to be tolerated.

Let us for a moment pause and give thought to what the return of the capacity of taking carbohydrate matter without its escaping as sugar implies. To begin with, for awhile there may be a passage of sugar with the limited supply of carbohydrate associated with the restricted diet. Then this sugar disappears, and, next, more and more carbohydrate can be taken without running off from the system as sugar with the urine. Surely this must indisputably mean that the system has regained a power that it had previously lost.

An important principle is involved in connexion with what I have just set forth, and all the facts stand in harmony with what may be rationally looked for. It is certainly a notable point that everything should work out as harmoniously as it does. The effect of carbohydrate food in health is diametrically opposed to its effect in diabetes. In health, as we well know, it contributes to the increase or to the maintenance of weight. In diabetes when sugar is being voided it does exactly the reverse. If it runs off as waste material with the urine it naturally cannot be expected to go towards maintaining or increasing weight. As a matter of fact it leads to decrease of weight through waste occurring and the wrong state of system induced by the abnormal presence of sugar that is in transit from the food to the urine. Who has not noticed the marked decline of weight that occurs in a diabetic before subjection to dietetic management and the rise that immediately follows its adoption? The circumstances in diabetes then are such as to lead to the supply of carbohydrate producing a loss, and restriction from it a gain of weight. The healthy person, on the other hand, gains weight upon its full supply and loses weight if the supply is restricted. Now in proportion as his assimilative power becomes raised so is the position of the diabetic brought into conformity with that of the healthy person and so is the necessity created for his being similarly dealt with. As long as carbohydrate food fails to be utilised its supply does harm. Directly the system regains the power of utilising it, it is found, as in the case of the healthy person, that it is wanted and that if it is not supplied the want is betokened by a decrease in weight and a decline of strength. The principle to put into force is to give it short of producing saccharine urine, and decreasing weight with sugar-free urine may be taken as meaning that the supply is not equal to what is permissible and moreover wanted.

In cases where the assimilative power is not recovered observation shows that the restricted diet is borne without the occurrence of loss of weight and it is permissible for me to state that the circumstance may be safely taken as a guide in practice. I know of patients who have gone on for years with the restricted diet with a thorough maintenance of weight. They are not the patients to bear the supply of bread. The system cannot want or be benefited by that which it has not the power of properly disposing of and allows to run off as waste material with the urine. It is only that which can be properly disposed of that can render service to the system.

The loss of weight attendant upon unneeded restriction from carbohydrate food may afford assistance from a diagnostic point of view. If at starting the case has not been properly diagnosed, and it should prove to be one where, from simply undue concentration of urine and the high specific gravity and the slight indication of reaction with the copper test often met with under the circumstances, an erroneous inference has been drawn and the patient has been unnecessarily put on the dietetic management for diabetes, a loss of weight, sometimes of a marked nature, will ensue. Equally also loss of weight will ensue if the case is one of mild glycosuria and it is treated as one of ordinary diabetes. Rightly appreciated the result noticeable will be suggestive that curtailment of the supply of carbohydrate matter is being carried to an uncalled-for extent.

From the remarks I have made it will be gleaned that food stands as the great factor in the treatment of diabetes. As I have stated the object really before us for attainment is restoration of assimilative power. My experience leads me in an explicit manner to say that I believe this is promoted by the medicinal employment of opium or its alkaloids, and I think the view accords with the result of the general experience of others. The older physicians, before the dietetic management of diabetes stood in the position it

Digitized by Google

now does, empirically arrived at the conclusion that an amelioration accrued from the administration of opium.

Although the great factor in relation to the amount of sugar eliminated, food is evidently not the only one. The pathological condition which stands at the foundation of the action constituting the immediate source of the elimination is presumably influenced by incidental circumstances. In many cases, it is true, it may be noticed that the assimilative power stands with remarkable constancy at a fixed point for a prolonged period, but in others evidence is presented pointing to the patient being liable to be influenced by collateral conditions, especially of a mental nature, having the effect of altering to a greater or less extent the amount of sugar eliminated upon a given quantity of carbohydrate when sugar is being passed, and of leading to a certain amount of elimination when the urine has previously been in a non-saccharine state.

The phenomena I have hitherto been speaking of belong to what is appropriately styled the alimentary form of diabetes, which I would certainly say from my own experience is far more common than the other, but at the same time is not the form that most frequently finds its way into the wards of the hospital. Besides the cases controllable by attention to food we meet with others in which no amount of dieting will remove the sugar from the urine. These present us with the classical type of the disease and may be grouped into what may be called the grave form of diabetes, a form belonging especially to the period of life below middle age. A superadded condition exists which leads to sugar being derived from the tissues as well as from the food. The glucoside constitution of the nitrogenous principles of the body supplies an intelligible source for sugar, all that is wanted being a pathologically developed ferment possessing the power of breaking them up with the liberation of their sugar molecule just as occurs with amygdalin in presence of emulsin.

Cases progress from the alimentary form into the grave form and it is upon the extent to which the progressive tendency exists that the issue depends. Amongst persons above the middle period of life the progressive tendency is usually susceptible of being held in check, and often, as I have shown, progress even in the opposite or right direction is to be brought about. I think it may be definitely said that allowing the complaint to run on in an uncontrolled state promotes the passage from the alimentary into the grave form, but undoubtedly there is nothing like the same proneness for the occurrence of the passage amongst elderly that there is amongst young people. It is indeed the strongly marked progressive tendency that gives the formidable nature to diabetes in young subjects. A striking analogy is presented to the progressive diseases of the nervous system; and (but this is a point that time precludes my entering into here) may we not have at the foundation of diabetes a wrong nerve condition implicating and operating through the vaso-motor system? In its early stage the complaint may be just as controllable in a young as in an elderly person, but as time goes on the difference becomes manifest and it is found in the former that through the advance that has insidiously taken place the measures that before produced a satisfactory state no longer succeed in doing so. The rate of progress may vary considerably. In some cases with an inherited history I have known it extend over many years.

And now, Mr. President and Gentlemen, let me in concluding this lecture express the hope that I have succeeded in clearly placing before you what is in my own mind as the outcome of the life-long attention I have given to the subject upon which I have addressed you. The views I have set forth have sprung entirely from experimental physiological work on the one hand, and from practical experience in connexion with diabetes on the other. With this foundation they harmonise with the assemblage of facts to be dealt with belonging alike to physiology and pathology, and at one and the same time they bring the whole matter into a state of great simplicity and supply a working basis upon which the treatment of diabetes may be rationally and reliably conducted. With the glycogenic doctrine the teachings of diabetes are absolutely irreconcilable, and it may, moreover, be said that modern research has removed the support upon which it was originally based. And yet the doctrine still lingers in the mind, influencing its conceptions and shaping its views, for persons seem unable to look at the points belonging to the subject otherwise than through the prepossessions that have been engendered thereby. The chapter, however, will have, sooner or later, not simply to be revised but completely rewritten; and the sooner this is done the better, I feel I am justified in saying, will it be for the right comprehension of diabetes by the medical profession.

HERNIA OF THE ABDOMINAL CICATRIX AND OPERATIONS FOR ITS CURE.[1]

BY ALBAN DORAN, F.R.C.S. ENG.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

HERNIA of the cicatrix after abdominal section is unfortunately an accident of no great rarity. A mere digital protrusion may be kept back by pressure skilfully applied. If, however, it is suffered to attain a large size it may prove more troublesome than the disease for which the operation was performed. It may also become in itself a direct source of danger demanding surgical steps for its relief. The late Mr. Greig Smith, the loss of whom we all regret, clearly refers to the less advanced type of ventral hernia when he lays down his principles of treatment in his well-known work.[2] Indeed, it would at first seem as though he referred to primary ventral hernia independent of any surgical wound, but he distinctly states that "ventral hernia so-called is simply a stretching of scar-tissue which permits the abdominal contents to escape through the parietes and to bulge outwardly under the skin." Further,[3] in his paragraphs on hernia after operation, he distinctly refers back to the same passage. Hence he is clearly speaking of surgical ventral hernia. Mr. Greig Smith continues:[4] "There is no narrow neck as in umbilical hernia and no dissection of skin from parietes by burrowing omentum or intestine as in umbilical hernia. The hernial sac is simply stretched peritoneum; the coverings are stretched cicatricial tissue with a little fat and stretched skin. To cure this condition it is necessary to remove or push aside the redundant and attenuated tissues and bring into contact and keep in contact the thick and non-yielding parietes. To do this satisfactorily it is rarely necessary to enter the abdominal cavity." Here follows a description of his operation where the cavity is not opened.

Deeply regretting that Mr. Greig Smith, who was living when I began to prepare these notes last autumn, is no longer amongst us, I must be allowed to respectfully observe, in the interest of patients and operators, that the deceased surgeon's description of surgical ventral hernia can only apply to a very early stage of that troublesome complication. Even at that stage I should hesitate to operate without opening the peritoneum. When the hernia has developed further, so far from there being "no narrow neck" there may be a very tense narrow neck as in two of the four severe cases presently to be described.[5] Secondary sacs and burrowing of omentum and intestine are observed in this form of rupture just as in umbilical hernia. Firm adhesion of intestine to the cicatrix is frequent. I will now give the notes of four particularly severe cases in my own practice where all the above noted complications were detected. An operation was demanded on account of those complications which were successfully relieved. I must add that I am not sanguine about the ultimate result as far as complete immunity from recurrence is concerned. The four cases simply show that hernia of the cicatrix is a serious condition.

CASE 1. *Hernia of ovariotomy-wound two years; large sac; secondary pouch; circular sharp edged neck with intimate adhesion of the transverse colon in the middle of cicatrix.*—A single woman, aged fifty-one years, was admitted into my wards at the Samaritan Hospital in June, 1895. On April 10th, 1893, the late Mr. Hulke removed an ovarian tumour. The incision, Mr. Bland Sutton kindly informed me, was closed by a single series of waxed silk sutures. She remained six weeks in bed after the operation and wore strapping all that time. She did not have a belt till a month

[5] Dr. Benno Schmidt in speaking of hernia of the abdominal cicatrix rightly observes that "as a rule the neck of the sac has not a sharp border" ("Die Unterleibsbrüche," Billroth und Luecke, Deutsche Chirurgie, 1896, p. 357).

Digitized by Google

after her discharge from the Middlesex Hospital, but went to work with a linen binder round her abdomen. The belt was not made to measure and did not fit. The patient told me that she first noticed a swelling in the abdominal scar eight months before admission—that is, in November, 1894, or over one and a half years after the ovariotomy. It caused her extreme inconvenience and she could not earn her living. She declared that otherwise her health was good; unfortunately she concealed the fact that in April, 1895, she had been seized with a slight convulsion which lasted for a few minutes. The abdominal walls were found to be very relaxed. The cicatrix was about four inches long and S-shaped. In the middle and nearer its upper than its lower limit was a circular hernial aperture nearly two inches wide. The edge felt sharp excepting above, where a soft body which I at once recognised as intestine adhered to it. When the patient coughed intestine escaped freely. On June 25th, 1895, I operated. I mapped out an incision carried all round the redundant skin and then dissected deeper on the right of the cicatrix proceeding cautiously till the peritoneum was opened. Then a deep secondary pouch was found, passing to the left under the left rectus and full of adherent omentum which I set free. The sharp circular neck of the hernia was now reached. The peritoneum was reflected over it, passing on to the sac, and half an inch of the transverse colon was firmly incorporated with the upper part of the neck. I cut into the peritoneum all round the ring, passing in front of the adherent colon, dissected away the pouch which extended far to the left under the skin, and then cut away the redundant integument. Then I trimmed the sharp aponeurotic border of the neck of the sac and dissected off the adherent colon, a difficult process as the fibrous tissue was incorporated with the wall of the intestine and there was much bleeding. The liberated colon slipped up high above the wound. I sewed together the cut edges of the peritoneum with stout catgut. Then I closed the aponeurotic layer, which had been freely trimmed so as to destroy the abdominal aperture, with the same material. The integuments were united with interrupted silkworm-gut sutures. All the silkworm-gut sutures were removed by July 3rd. On the 18th the patient had an attack of hemiplegia; spastic contraction of the right hand was marked. I sent her to St. Mary's Hospital in August, where she remained under the care of Dr. Maguire for a few weeks. The new wound healed well. The patient tried to do a little work in the autumn and admitted that the operation had given her great relief. No longer did a mass of intestine come out of the abdominal cavity on the least exertion. A fatal attack of paralysis occurred in December, 1895. The wound was quite strong when she died.

CASE 2. *Hernia of hysterectomy-wound four years; large sac with large secondary pouch; circular sharp-edged neck in the lower extremity of the cicatrix; firm adhesion of the small intestine and omentum to the fundus of the sac.*—The patient, a single woman, aged fifty-two years, had undergone varied treatment for uterine fibroid. Four years before I saw her an exploratory incision was made and six months later Dr. Remfry removed the uterus by supravaginal hysterectomy using the serre-nœud.[6] Soon after leaving the hospital a rupture developed. The patient left off her belt at the end of two years. The rupture grew larger and caused attacks of severe pain. The patient was referred to me by Dr. Frederick McCann and came under my care on March 9th, 1896. There was a hernial protrusion at the lower end of a cicatrix nearly five inches long. On reducing a mass of bowel I could feel the sharp neck of the sac about one and a half inches in diameter, and as the edge was soft and blunt on the right side I concluded that intestine must be adherent there. The fundus of the bladder rose in the groin completely to the right of the hernia and below it. On March 13th I operated, managing the integuments as in Case 1. I found the omentum strongly adherent to the sac when I dissected up the skin to the right of the cicatrix. After tying and dividing the omentum I explored the left side of the sac from within. I came upon a long coil of small intestine firmly adherent to the peritoneum close to the skin incision which I had mapped out on the left side of the much-stretched cicatrix. A small piece of the serous coat of the intestine was torn before I could set the gut free; the adhesions extended to the left iliac fossa far beyond the hernia. Then I found very firm omental adhesions to the under side of the upper part of the scar; one indeed lay above it, whilst another lay in a secondary pouch of peritoneum which ran under the rectus muscle an inch beyond the left limits of the main hernial sac. The omentum was hard to draw out of this secondary pouch. I now completed the excision of the sac by cutting through all the tissues on the left. The excised parietes were pyriform in outline. I found some moderately firm adhesions of the ascending colon to the parietal peritoneum on the right, to the neck in fact. Most of the neck had already been trimmed away during the separation of the complicated adhesions. I applied deep interrupted silkworm gut sutures through all the tissues including the peritoneum; then sewed up the aponeurotic layer with a continuous No. 3 silk suture, after which the silkworm gut threads were tied. The interrupted sutures were removed on the tenth day. In the course of the above operation I found that the stump of the uterus amputated four years previously was reduced to a broad, flat ligament which ran over the left side of the bladder and was lost above in the lower angle of the wound immediately below the hernial sac. The patient made a rapid recovery, but I enjoined long rest and she attended to my advice. In the summer she was in excellent health; the new cicatrix was firm and all the discomfort which she felt before operation had passed away.

CASE 3.—*Hernia of cicatrix of incision on the outer border of the right rectus for two years; enormous sac; no true neck; elongated secondary pouch with narrow neck almost strangulating the omentum; intimate adhesion of the omentum to the fundus of the sac; removal of the appendages for papillomatous disease.*—A woman, aged twenty-eight years, married eleven years, two children, the youngest eight years old, was sent into my wards in the Samaritan Hospital on March 21st, 1896. There was a large hernia of a cicatrix which extended along the outer border of the right rectus from the level of the umbilicus to the pubes. On coughing a large protrusion developed and the greater part of the intestines slipped into the sac when the patient walked about. There was also a tender swelling to the right of the uterus. The original mischief, as I learned from Mr. Lunn, was a neglected miscarriage, and she was so ill afterwards, in February, 1894, that she was unconscious when her friends took her into the Marylebone Infirmary. A large pelvic abscess was opened through the parietes and the peritoneal cavity was irrigated and drained. The patient made a good recovery but did not take care of herself. Severe pelvic pain and the constantly enlarging hernia made her seek for operative relief. On April 7th, 1896, I operated with the assistance of Mr. Corrie Keep. I made an elliptical incision around the distended integument, and dissected up the skin to the right. There was very dense cicatricial tissue beneath it, including, so to speak, a large mass of omentum. This was divided and then I explored the pelvis. The left as well as the right appendages were extensively diseased. After aspirating the right tube there was no difficulty in removing the diseased parts and securing the pedicles. The tubes were cystic and papillomatous degeneration was detected in both. I then turned once more to the hernia. Much thickened peritoneum was trimmed away, including a secondary pouch with a very narrow neck full of adherent omentum running under the skin in the lowest part of the wound. The cut edges were dissected up from the muscular layer in front (a matter of some difficulty) and united with a continuous suture of No. 1 silk. Silkworm-gut sutures, interrupted, were passed through the skin, muscle and aponeurosis and tied. The patient made a good recovery. The sutures were removed on the tenth day. The patient remained perfectly comfortable. Unfortunately, in March, 1897, a small digital protrusion developed in the lower angle of the wound. This is a hernia of the milder form such as will presently be described. It gives no inconvenience and is held back by a bandage. Of course, if neglected it would become as serious as before.

CASE 4. *Double hernia of median abdominal wound; exploratory incision three years; large sac with two secondary pouches and long, narrow neck; small sac with narrow circular neck lower down; strong adhesion of small intestine and omentum to fundus of large sac.*—A woman, aged twenty-seven years, married six years, last confinement five years and three months previously, was sent to my wards by Mr. Corrie Keep on July 5th, 1896, for the relief of a large hernia of the abdominal cicatrix. The history was remarkable. Her mother stated that she had several fits when a child.

[6] The period was never seen after this operation.

Digitized by Google

Dr. Findlater, of Edgware, and Mr. Sutton kindly sent me particulars of the operation where the wound was made. She was admitted into the London Infirmary in November, 1893, as a mental case. Her bowels were very stubborn from the date of her admission. On April 16th, 1894, they had not been opened for three weeks. She believed that she had swallowed a cork. The abdomen was greatly distended and the integuments were red, as though there was an abscess. The breath smelt fæcal and grumous liquid came away after enemata-like motion in cases of obstruction. At 8.30 P.M. on April 16th Mr. Bland Sutton operated and found no mechanical obstruction and nothing remarkable. The bowels except the sigmoid flexure were quite empty. At 10 P.M. she got out of bed, tore off all her dressings, and passed an enormous stool. During convalescence she was restless, but not more so than before the operation. About nine months before I saw her the scar began to bulge. Mr. Keep had kept her under observation for some time and found that the hernia was steadily increasing in size. The patient suffered badly from dragging pains and earnestly begged for operative relief. The hernial pouch was pear-shaped and nearly five inches long, including the entire cicatrix. It was deeply pigmented, as though the brown line which probably developed after the patient's only pregnancy had increased in width by deposit of fresh pigment during cicatrisation. On further examination I found that the hernia was double, as I could feel an elliptical gap one inch long in the aponeurotic layer near the upper part of the wound and another admitting the tip of the forefinger at the lower angle. On coughing intestine could be felt issuing from both gaps and the whole cicatrix bulged forwards as a large sac. On July 8th, 1896, I operated with the assistance of Mr. Targett. I mapped out a pyriform incision in the skin around the sac and cautiously dissected up the integuments on the left. I came at once upon a coil of ileum which adhered rather firmly to the sac which issued from the upper gap; it could not be detached without damage to its serous coat, which was repaired. The ileum then fell back into the abdominal cavity. There were several omental adhesions on the upper part of the sac and even higher on the parietes above the hernia. The omentum was set free, including a long and tough band which turned upwards and adhered to the transverse colon, drawing it down below the level of the umbilicus. Two secondary pouches existed in the sac wall, burrowing to the left under the skin, but they were empty. The peritoneum after the excision of its two sacs was separated from the aponeurotic tissues and its edges united with fine catgut and the two gaps in the aponeurosis carefully trimmed and united with stout catgut. The lower or circular gap in the wound was occupied by a short process of peritoneum containing no adherent intestine or omentum; it was readily trimmed away. The integuments were brought together with interrupted silkworm-gut sutures.

During convalescence the patient had symptoms of hystero-epilepsy and was very violent from the first, yet there was absolutely no trouble due to flatulence or any difficulty in getting the bowels open. All the skin sutures were removed on the eleventh day and the patient was discharged on the twentieth day. A month later she was reported as quite free from any of the trouble due to the hernia; she was under treatment for her nerve symptoms in the Marylebone Infirmary.

It is clear that the above cases were forms of ventral hernia which could not have been treated after the fashion recommended by Mr. Greig Smith, and they displayed conditions which he seemed to consider as rare or non-existent in this kind of rupture. Operations of the kind just described are not without risk. I know of two fatal cases, in one of which inflammation of the parotid occurred.

In analysing these four cases the first thing to note is the apparent cause of the hernia in each. In none could either the operator or his method be blamed. Thus the patient in Case 4 was half insane and considering her behaviour directly after the first operation it is remarkable that she did not suffer from worse complications than hernia. In Case 1 the patient chose to wear an ill-fitting belt from the first without acquainting Mr. Hulke of the fact. How far her cerebral disease was the cause of carelessness on her part I cannot say. Case 3 is easily understood the incision was made through inflamed tissues for the relief of suppuration and drainage was necessary. There remains Case 2. Here the operator had to cut through an old cicatrix made for exploratory purposes and he found it best to use the serre-nœud. Under such conditions hernia may develop notwithstanding the greatest care. As with these four cases so it is as a rule with most other instances of hernia of abdominal cicatrices, save where there has been manifestly undue hurry in removing the sutures or where the peritoneum has been taken up too far from its cut edge or where the operator has evidently been careless in regard to the bandaging or strapping of the wound. In all four cases the patient eagerly solicited an operation for the relief of her condition. In Case 3 an operation was urgent, the discomfort was extreme, and the hernia very large. The patient in Case 2 also suffered badly, the neck of the sac was very sharp, and, as in Case 3, the patient was perfectly competent to decide for herself. In the latter respect the matter was somewhat different in the first and last cases. In Case 1 the patient concealed from us the fact that she had suffered from disease. Her friends admitted that she dreaded to let the truth be known lest she might lose a situation. I fancy that I should not have operated had I known about the fit; hemiplegia is a much more serious matter than ventral hernia, and the attack after the operation gave me great anxiety. Still, there was a dangerous hernia with a narrow neck causing extreme discomfort which the operation entirely relieved. The patient in Case 4 also had serious nerve disorder, but the hernia was causing her misery and by means of vigilant nursing the patient recovered from the operation with complete relief from all abdominal trouble. The nerve disease was of a much less grave character than in Case 1 and the hernia had undoubtedly aggravated it. In all, the peritoneum of the main sac was closely incorporated with the skin so that it could not be dissected off. On the other hand, the secondary sacs did not in any case adhere to the skin or aponeurotic tissues; indeed, in Cases 2 and 3 I discovered the secondary sac by inverting it when dragging an omentum which proved to be adherent to its inner wall. Strictly speaking, a secondary sac is only a lateral offshoot of the main sac which not being pressed firmly forwards against the cicatrised integuments does not rapidly contract adhesions.

The neck of the sac was a narrow ring with sharp edges in Cases 1 and 2. In Case 4 there were two sacs; the larger had a neck consisting of a gap between the recti. The neck of the lesser sac was a more circular space near the lower angle of the wound. The upper sac was clearly the older. The lower admitted intestine and omentum but was free from adhesions, it represented an earlier degree of rupture as in cases which will presently be related. The diagnosis of intestinal adhesions to the sharp ring in Cases 1 and 2 was easily made. In Case 3 there was no true neck; in this case there was a secondary pouch with a very narrow neck almost strangulating the omentum. In Case 1 the neck of the sac was nearer the upper than the lower extremity of the wound. In Cases 1, 2, and 4 no drainage-tube had been inserted at the first operation, but in Case 2 the lower end of the wound had been filled by the stump of a uterine fibroid. Case 3 was drained; the wound was lateral. The tendency to adhesion of omentum and intestine to the parietes behind the neck of the sac was marked in these cases. It is very usual to find adhesions behind a normal cicatrix when a second ovariotomy is performed long after the first.

Turning to the steps of the operation it is self evident that the operator should map out his incision through the protruding skin and then cut through the skin at a point which seems safe. Complete excision cannot be safely effected till towards the end of the operation. If the peritoneum be not closely adherent to the integuments at the selected point so much the better, but the knife often comes on omentum (Cases 2 and 3) or intestine (Case 4) at once. Thus the above cases show that, as I have before remarked, a neglected hernia of the cicatrix is a serious condition and involves complications that demand operative relief. Yet when they are relieved it is not certain that the hernial protrusion will not recur (Case 3). The aponeurosis and muscle are too often irretrievably damaged; the operation is rather for the liberation of intestine and omentum than for complete restoration of the parietes to their previous normal condition.

I will now turn to the consideration of hernia of the cicatrix in its earlier stages when no operation is required. I have seen a very large number of ruptures of this kind, but I think that it is only fair that I should confine myself at present to cases where I was the original operator. I have taken considerable pains to search for after-histories and shall be glad of any further information.

CASE 5.—In February, 1891, I operated on a woman, aged

Digitized by Google

thirty-five years, who was fairly nourished, and removed two ovarian cysts. The incision, two and a half inches in length, was closed with five deep silkworm-gut sutures and a continuous horsehair suture was applied to the integuments along its lower half. These were removed on the seventh day. Fourteen months later the wound was strong. In August, 1894, I felt a small gap in the aponeurotic layer large enough to admit the point of my little finger. In May, 1897, I found that the gap had not grown larger and that there was distinct impulse over it on coughing. This was one of Mr. Greig Smith's type of ventral hernia, I suspect. It caused the patient no inconvenience. I never remove all the sutures on the seventh day now but I doubt if their early removal caused the hernia. No drainage-tube was used in this or in the next two cases.

CASE 6.—In November, 1891, I removed a large tubo-ovarian cyst from a rather thin woman, aged forty-six years (II-para). The incision, three inches long, was closed with six deep silkworm-gut and three superficial horsehair sutures. Half the deep sutures were removed on the seventh day, the rest on the tenth. I often saw this patient afterwards. In October, 1894, I detected a minute hernia in the middle of the cicatrix; on coughing it formed a protrusion as large as a cob-nut. This case is almost identical with the last. Let it be noted that here as in the next case the hernia was not in the lower angle of the scar.

CASE 7.—The patient in this case was a multipara, aged forty-three years. She was rather fat. In July, 1893, I removed the appendages for chronic disease through an incision not quite three inches in length. I closed the wound with five deep and one superficial silkworm-gut sutures. By the eighth day they were all removed. A year later the cicatrix was strong. I saw the patient this spring. There was a small hernial protrusion in the middle of the cicatrix admitting the tip of the forefinger.

In a case of ruptured tubal pregnancy where I drained a slight hernial protrusion developed five years afterwards. Lastly remains a curious case where I removed both ovaries six years ago for checking the growth of a moderately large fibroid in a rather stout subject, aged thirty-nine years. The tumour diminished steadily in size. It happened, however, that a small pedunculated growth of the shape and size of a large brass button lay in front of the tumour in the median line so that it pressed against the scar. No doubt the pressure of the belt acted prejudicially under these exceptional circumstances. The pedunculated outgrowth pressed the cicatricial tissue apart and has come to lie under the skin. It gives no inconvenience though it may prove troublesome when the uterus becomes much smaller from dragging on the scar.

It is remarkable that though I at one time used the drainage-tube very freely I have only once seen a hernia form in its track and that was in one of the cases above noted. Thus an incipient hernia of a cicatrix is not very serious provided that it be carefully watched, the patient being intelligent and prompt to carry out the advice of her medical attendent. No operation is demanded in this form of hernia. Were it necessary I should hesitate to follow Mr. Greig Smith's advice, leaving the sac unopened. In the smallest protrusion there might be an omental or even intestinal adhesion. Experience shows that a small hernia may be kept back indefinitely by careful bandaging so as to remain in a stationary condition. The patient must be warned to be particularly cautious if she finds that she is growing stouter, for in a corpulent subject scar-tissue is apt to grow weak, whilst fat omentum tends to push its way into the sac to which it soon becomes adherent.

The cause of hernia is manifestly non-union of the cicatrix in one of the layers or stretching of the cicatrix. Hence the best method of ensuring union, in other words, the best kind of suture, is a matter of great importance. Unfortunately this question is by no means settled. According to my own experience I am no believer in the superiority of any method. I have known hernia to occur where the wound had been closed by a row of interrupted sutures passing through all the layers. I have seen just as bad hernia when the aponeurotic layer had been united by a separate continuous catgut suture. Deep interrupted sutures, whatever has been said to the contrary, must surely allow of the normal union of each layer as a rule, for I have examined many scars of wounds so treated ten or more years earlier by Spencer Wells and found them sound, though I have detected hernia in similar cases once under that surgeon. Separate union of the aponeurosis is no guarantee against the development of a hernia. Many operators (Martin, Winckel, and Chrobak) admit this fact. Mr. Cripps goes so far as to declare that a continuous catgut or other suture applied to the aponeurosis actually weakens the wound, being a foreign body.

In operations such as those which I have described for the cure of a hernia separate union of the aponeurosis is absolutely necessary as the edges of that layer gape widely and have to be trimmed and brought together. The peritoneal layer may also in these cases need separate suture. When on the other hand a wound through normal tissues is closed the structures on each side are healthy, free from atrophic changes, and easily brought into apposition by deep interrupted sutures. Statistics about the relative merits of sutures are untrustworthy for several reasons. I spoke on this subject at the Geneva meeting of the International Gynæcological Congress in 1896,[7] and noted that when an operator published better results after a change of treatment it often implied that he had become a better and more experienced surgeon. There was a more serious fallacy, for some of the same speakers who issued these records laid stress on the fact that a hernia did not always develop until many years after the operation. Here they were quite correct; yet with that knowledge they published the results of five, ten, or twenty years' experience with an older method and compared them with what they are pleased to call the more satisfactory results of two or three later years' experience of a newer method. This grave source of fallacy is prominent in the "Report of the Discussion on Abdominal Sutures and Abdominal Hernia at the Vienna Meeting of the Deutsche Gesellschaft für Gynäkologie, June, 1895."[8] All manners of suture seemed to answer in the practice of different authorities who at the same time admitted that none guaranteed against hernia. Since I prepared these notes early last autumn Professor La Torre's important essay on the same subject has been published. I agree with him that up to the present day we lack precise knowledge on many questions relating to hernia and sutures. The sixty-three opinions which he has collected since the German Congress are very conflicting and in many cases seem based on insecure foundations such as I have just indicated.[9]

Bossi of Genoa represents the extreme school which advocates suture of each layer separately. He unites the peritoneum in this manner, and there are British[10] and other operators who agree with him. In cases of hernia like Cases 1, 3, and 4 in this paper where much peritoneum is trimmed away separate suture of the cut edges of that membrane may be necessary else apposition will be imperfect. I strongly object to this practice, however, after an ordinary abdominal section, for I know well that union of the serous layer begins very early even when a single set of deep interrupted and not very close sutures are applied. Nearly twenty years ago I found complete union of the peritoneum in necropsies on patients who had died with septic or other bad symptoms within a few days after ovariotomy.[11] No doubt the wound often gapes when sepsis has lasted for several days, but not through the fault of the suture.[12] On the other hand, Martin and Mr. Greig Smith represent the school diametrically opposed to Bossi. Martin holds that complicated methods appear doubtful. He passes silk threads through all the layers. It is true that he applies a few superficial sutures to the skin, but more to ensure speedy healing of a cutaneous wound than to avoid hernia. Mr. Greig Smith advocated the deep suture ("mass-suture," as he called it) on good theoretical grounds, though he gave directions for the application of continuous sutures in separate layers. He looked on "the separate suturing of

[12] Ibid., p. 130. Very fat subject; pyæmia; death on twelfth day. "The peritoneal borders of the wound were so feebly united by lymph that they came apart in gentle traction at the necropsy." Thus at least they were united. Of course, the union was weak in these early and fatal cases. What I endeavoured to demonstrate above is that the union of the peritoneum is speedy without separate sutures.

Digitized by Google

each parietal layer as a refinement always, and as a superfluity usually, provided that the single group suture is properly placed."[13]

I myself always apply deep interrupted sutures and take up not more than one-eighth of an inch of the peritoneum. If too much serous membrane be taken up it will become everted and prevent the aponeurotic layer from uniting; thus a hernial pouch is actually manufactured by the operator. On the other hand I disapprove of the practice of leaving the serous layers out of the stitching altogether. When sutured the peritoneum unites rapidly and thus cuts off its great cavity from the wound—an aim we all desire. The suture track surrounded by lymph never seems to endanger the peritoneal cavity. The fibres of the rectus muscles must be included in the sutures else they will retreat inside their sutured sheath. When ordinary precautions are taken there will be no fear of suppuration of the sutured muscle. The same management is necessary for the closure of muscle in an incision away from the middle line. I often apply a few superficial sutures to the integument, after Spencer Wells's and Martin's practice, so as to make a sightly scar. In some very thin and in most very stout subjects I unite the sheath of the rectus with a continuous buried suture. In a very thin subject this prevents all danger of imperfect union from eversion of the sutured line of peritoneum. In a very stout patient I think that it is advisable to suture the sheath separately. Mr. Greig Smith when arguing against separate suture of each layer as an absolute necessity rightly observes that as young cicatricial tissue is the same for all the layers, and as each layer will certainly appropriate its own bundle of fibres from the common stock, little harm can be done if apposition be not accurate. Unfortunately this apposition may be very inaccurate in a fat wound, the subcutaneous and subserous adipose tissue being likely to form a junction at one or more points, and healing is relatively slow. The separate suture neutralises these dangers. I need hardly say that it must be gently applied, for one of the evils of the separate layer system of suturing is that it takes up time and each layer is exposed to much handling. On the other hand, the application of the deep sutures in a very fat wound may involve rough handling. The nozzle of most needle-holders is apt to bruise the fat. Hence I prefer to pass a large Péan's pedicle needle through the wound, then to thread it, and lastly to withdraw it. In an average or a thin wound it is handier to pass a curved or straight suture needle ready threaded through the tissues; Wells's well-known method, though not essential, as he believed, is the best, as the layers are the least disturbed if the needle be pushed through the serous layer outwards on each side. The deep sutures should be removed in part about the ninth day. It is best to take out the remainder within the end of the first fortnight. Still, better too late than too early is the rule for the removal of sutures. I need hardly say that sutures must be clean when applied and not tightened too much, and that the wound must be carefully supported by strapping and bandages. The operator must further remember that the most dangerous enemy to the wound is the steady pressure of flatulent intestine behind it.

The material for suture is not a matter of primary importance as far as our present subject is concerned. I much prefer silkworm-gut to silk, but the latter material is used and commended by many experienced operators. For the aponeurosis, where a continuous suture is applied, stout catgut or No. 1 or 2 silk is the best material. Fine catgut answers best to unite muscular tissue in abdominal wounds away from the median line.

In conclusion, I must admit that I feel sceptical about perfect success even with all the precautions which I practise. Martin rightly pointed out at Vienna in 1895 that the entire discussion on hernia of the abdominal wound was not on a sound basis, for different abdominal wounds healed very variously. Secondly, reports on the value of any one method are open to fallacies as I have already demonstrated. Lastly, the patient is often to blame for the complication. She is apt to discard the proper supports very early and in other ways to disregard advice. Hence it is the duty of the surgeon to warn her very strongly. For, as we have seen, a hernia of the abdominal wound may develop into a very ugly complication demanding surgical treatment which however necessary and justifiable is seldom in every respect satisfactory.

ON THE VALUE OF OLIVE OIL IN THE TREATMENT OF TYPHOID FEVER.

BY OWEN F. PAGET, M.B., B.C. CANTAB.

DURING my residence in Fremantle, Western Australi, it has been my lot to attend a large number of patients suffering from typhoid fever (well over 100) who were placed under the most disadvantageous circumstances, many of them living in tents and many of them unable to obtain any form of fresh milk. Yet my percentage of death is *nil*, and this is the more remarkable seeing that among patients removed to the hospital, where they are properly attended to and receive suitable nourishment, the percentage was as high as 20 in 1896 and 11 in 1897 with better accommodation.

Now this success, though undoubtedly to some extent due to good fortune, I attribute very largely to the use of salad oil in this disease. Nearly all typhoid fever patients when they first come under observation are suffering from constipation or diarrhœa; during constipation the "typhoid bacillus" acquires its power of developing—it is rare indeed for a patient not to have suffered from fæcal accumulation either before or during the commencement of the disease, for though accumulation may not always have been apparent, irritative diarrhœa having masked its presence, yet I am fully convinced of its occurrence in nearly all, if not all, cases. This constipation is followed by diarrhœa and a gradual solution of the fæcal accumulations caused by the pouring out of mucous and other fluids from the intestine. These fæcal solutions being intensely irritating help to inflame the already infected Peyer's patches and, in addition, give rise to violent peristalsis, preventing rest which is so important to inflamed regions. Added to this there is the enormous drain of fluid from the intestinal mucous surface. Now the fluid poured out is of course to a certain extent reabsorbed, but not before it is saturated with ptomaines; this necessarily causes violent constitutional disturbances in the patient, as high temperatures, cardiac paralysis, and intestinal paralysis with tympanites, exhaustion, delirium, and insomnia (with its accompanying uses of depressing drugs), sapræmia, septicæmia, pyæmia, secondary infection of glands, abscesses in bones, and death.

Now typhoid fever is merely an inflammation of Peyer's patches usually followed by ulceration. It will be a long time (if ever) before we can prevent this taking place. The onset is so insidious that even were we able, patients would not come early enough to the physician to give him the opportunity. The problem therefore resolves itself into treating an inflamed and possibly ulcerated surface, and the same laws hold good here as in any other part of the body—namely, rest and protection from irritating substances and collection of discharges. As a proviso it is necessary to remember that the patient must not starve. Now to keep these ulcers at rest and to remove irritating substances all that is needed is salad oil. This is given as an injection by the bowel, a large breakfast-cupful (from a quarter to half a pint) being used for the first four or five days at intervals of from twelve to twenty-four hours. Its benefits are distinct from the first, the temperature almost always falls 1° F., and the patient, instead of being irritable and restless, becomes calm and composed. After the fifth day it may be given every second day or left off entirely if the patient is having natural motions at least every twenty-four hours and if the temperature is steadily falling. There are, however, a certain proportion of cases which do not respond to injections; nothing comes away and the bowel is apparently empty, but it is in these very cases that the accumulation is worst. Suddenly the temperature runs up and the patient is seriously ill. Now it is the very virulence of the accumulation which, paralysing the gut, prevents its coming away. The remedy is simple. Give salad oil by the mouth, a large breakfast-cupful at a time; there is no need to be frightened, no harm will result, but the bowels will almost certainly respond, and injections are now able to manage the rest. If the first dose is without effect repeat after twelve hours.

Salad oil in typhoid fever is a perfect boon to the general practitioner. He can leave his patient fearing neither high temperature, delirium, insomnia, heart failure, or tymparites. I have never used the wet pack or other appliances for lowering the temperature (except sponging with vinegar and

Digitized by Google

lukewarm water), nor have I ever used any of the vaunted intestinal antiseptics, never having had a high temperature or other complications which did not respond to salad oil except in two cases. The first was that of a boy with hæmorrhage whose father and mother were always drunk and neglected him disgracefully. The second was a case of mitral stenosis which came under my care in a late stage of the disease. The patients in both cases ultimately recovered.

Lastly I would say that there seems to be no danger in conscientiously palpating and percussing the abdomen for the first week of the disease, and it is a valuable aid in estimating the disappearance of accumulations, though the temperature and general *bien-être* of the patient are now my usual guides.

Salad oil, one pint by the mouth and half a pint per rectum, has also given the most gratifying results in two cases of typhlitis under my care.

Fremantle, Western Australia.

SYPHILIS AS A CURE.

BY J. ROSS MACMAHON, M.B., C.M. ABERD.

THE above heading is somewhat paradoxical. We are accustomed to see and hear of syphilis in any other light than that of a cure. The following extraordinary and interesting case, however, manifests syphilis as a beneficent evil and although the curative element is dearly bought and the practical value little such is its academic interest that it is well worthy of record.
